Text version (November 25, 2015).

The latest version (and Russian edition) of this text accessible at beginners.re. An A4-format version is also available.

You can also follow me on twitter to get information about updates of this text: $@yurichev^1$ or to subscribe to the mailing list².

The cover was made by Andy Nechaevsky: facebook.

¹twitter.com/yurichev

²yurichev.com

Warning: this is a shortened LITE-version!

It is approximately 6 times shorter than full version (~150 pages) and intended to those who wants for very quick introduction to reverse engineering basics. There are nothing about MIPS, ARM, OllyDBG, GCC, GDB, IDA, there are no exercises, examples, etc.

If you still interesting in reverse engineering, full version of the book is always available on my website: beginners.re.

Contents

I.	Code patterns	1
1	A short introduction to the CPU	3
2	The simplest Function 2.1 x86	5 5
3	Hello, world!	7
	3.1 x86	7
	3.2 x86-64 3.2.1 MSVC-x86-64	9
	3.3 Conclusion	10
4	Function prologue and epilogue4.1Recursion	11 11
5	Stack	13
	5.1 Why does the stack grow backwards?	13
	5.2 What is the stack used for?	14
	5.2.1 Save the function's return address	14
	5.2.2 Passing function arguments	16
	5.2.3 Local variable storage	17
	5.2.4 x86: alloca() function	17
	5.2.5 (Windows) SEH	
	5.2.6 Buffer overflow protection	
	5.2.7 Automatic deallocation of data in stack	
	5.3 A typical stack layout	19
6	<pre>printf() with several arguments 6.1 x86</pre>	21 21

CON	TENTS	CONTENTS

Bibliography

CONTENTS Preface

There are several popular meanings of the term "reverse engineering": 1) The reverse engineering of software: researching compiled programs; 2) The scanning of 3D structures and the subsequent digital manipulation required order to duplicate them; 3) recreating DBMS³ structure. This book is about the first meaning.

Exercises and tasks

...are all moved to the separate website: http://challenges.re.

About the author

Dennis Yurichev is an experienced reverse engineer and programmer. He can be contacted by email: **dennis(a)yurichev.com**, or on Skype: **dennis.yurichev**.

Praise for Reverse Engineering for Beginners

- "It's very well done .. and for free .. amazing."⁴ Daniel Bilar, Siege Technologies, LLC.
- "... excellent and free"⁵ Pete Finnigan, Oracle RDBMS security guru.
- "... book is interesting, great job!" Michael Sikorski, author of *Practical Malware Analysis: The Hands-On Guide to Dissecting Malicious Software.*

³Database management systems

⁴twitter.com/daniel bilar/status/436578617221742593

⁵twitter.com/petefinnigan/status/400551705797869568

- "... my compliments for the very nice tutorial!" Herbert Bos, full professor at the Vrije Universiteit Amsterdam, co-author of *Modern Operating Systems (4th Edition)*.
- "... It is amazing and unbelievable." Luis Rocha, CISSP / ISSAP, Technical Manager, Network & Information Security at Verizon Business.
- "Thanks for the great work and your book." Joris van de Vis, SAP Netweaver & Security specialist.
- "... reasonable intro to some of the techniques."⁶ Mike Stay, teacher at the Federal Law Enforcement Training Center, Georgia, US.
- "I love this book! I have several students reading it at the moment, plan to use it in graduate course."⁷ Sergey Bratus, Research Assistant Professor at the Computer Science Department at Dartmouth College
- "Dennis @Yurichev has published an impressive (and free!) book on reverse engineering"⁸ Tanel Poder, Oracle RDBMS performance tuning expert.
- "This book is some kind of Wikipedia to beginners..." Archer, Chinese Translator, IT Security Researcher.

Thanks

For patiently answering all my questions: Andrey "herm1t" Baranovich, Slava "Avid" Kazakov.

For sending me notes about mistakes and inaccuracies: Stanislav "Beaver" Bobrytskyy, Alexander Lysenko, Shell Rocket, Zhu Ruijin, Changmin Heo.

For helping me in other ways: Andrew Zubinski, Arnaud Patard (rtp on #debian-arm IRC), Aliaksandr Autayeu.

For translating the book into Simplified Chinese: Antiy Labs (antiy.cn) and Archer.

For translating the book into Korean: Byungho Min.

For proofreading: Alexander "Lstar" Chernenkiy, Vladimir Botov, Andrei Brazhuk, Mark "Logxen" Cooper, Yuan Jochen Kang, Mal Malakov, Lewis Porter, Jarle Thorsen.

Vasil Kolev did a great amount of work in proofreading and correcting many mistakes.

For illustrations and cover art: Andy Nechaevsky.

Thanks also to all the folks on github.com who have contributed notes and corrections.

mini-FAQ

Q: Why should one learn assembly language these days?

A: Unless you are an OS⁹ developer, you probably don't need to code in assembly modern compilers are much better at performing optimizations than humans ¹⁰. Also, modern CPU¹¹s are very complex devices and assembly knowledge doesn't really help one to understand their internals. That being said, there are at least two areas where a good understanding of assembly can be helpful: First and foremost, security/malware research. It is also a good way to gain a better understanding of your compiled code whilst debugging. This book is therefore intended for those who want to understand assembly language rather than to code in it, which is why there are many examples of compiler output contained within.

Q: I clicked on a hyperlink inside a PDF-document, how do I go back? A: In Adobe Acrobat Reader click Alt+LeftArrow.

⁹Operating System

¹⁰A very good text about this topic: [Fog13]

¹¹Central processing unit

Q: I'm not sure if I should try to learn reverse engineering or not. A: Perhaps, the average time to become familiar with the contents of the shortened

LITE-version is 1-2 month(s).

Q: May I print this book? Use it for teaching?

A: Of course! That's why the book is licensed under the Creative Commons license. One might also want to build one's own version of book—read here to find out more.

Q: I want to translate your book to some other language. A: Read my note to translators.

Q: How does one get a job in reverse engineering?

A: There are hiring threads that appear from time to time on reddit, devoted to RE^{12} (2013 Q3, 2014). Try looking there. A somewhat related hiring thread can be found in the "netsec" subreddit: 2014 Q2.

Q: I have a question...

A: Send it to me by email (dennis(a)yurichev.com).

This is the A5-format version for e-book readers. Although the content is mostly the same, the illustrations are resized and probably not readable. You may try to change scale in your e-book reader. Otherwise, you can always view them in the A4-format version here: beginners.re.

About the Korean translation

In January 2015, the Acorn publishing company (www.acornpub.co.kr) in South Korea did a huge amount of work in translating and publishing my book (as it was in August 2014) into Korean.

It's now available at their website.

The translator is Byungho Min (twitter/tais9).

The cover art was done by my artistic friend, Andy Nechaevsky : facebook/andydinka.

They also hold the copyright to the Korean translation.

So, if you want to have a *real* book on your shelf in Korean and want to support my work, it is now available for purchase.

¹²reddit.com/r/ReverseEngineering/

Part I

Code patterns

Everything is comprehended in comparison

Author unknown

When the author of this book first started learning C and, later, C++, he used to write small pieces of code, compile them, and then look at the assembly language output. This made it very easy for him to understand what was going on in the code that he had written. ¹³. He did it so many times that the relationship between the C/C++ code and what the compiler produced was imprinted deeply in his mind. It's easy to imagine instantly a rough outline of C code's appearance and function. Perhaps this technique could be helpful for others.

Sometimes ancient compilers are used here, in order to get the shortest (or simplest) possible code snippet.

Optimization levels and debug information

Source code can be compiled by different compilers with various optimization levels. A typical compiler has about three such levels, where level zero means disable optimization. Optimization can also be targeted towards code size or code speed.

A non-optimizing compiler is faster and produces more understandable (albeit verbose) code, whereas an optimizing compiler is slower and tries to produce code that runs faster (but is not necessarily more compact).

In addition to optimization levels and direction, a compiler can include in the resulting file some debug information, thus producing code for easy debugging.

One of the important features of the 'debug' code is that it might contain links between each line of the source code and the respective machine code addresses. Optimizing compilers, on the other hand, tend to produce output where entire lines of source code can be optimized away and thus not even be present in the resulting machine code.

Reverse engineers can encounter either version, simply because some developers turn on the compiler's optimization flags and others do not. Because of this, we'll try to work on examples of both debug and release versions of the code featured in this book, where possible.

¹³In fact, he still does it when he can't understand what a particular bit of code does.

A short introduction to the CPU

The CPU is the device that executes the machine code a program consists of.

A short glossary:

- **Instruction** : A primitive CPU command. The simplest examples include: moving data between registers, working with memory, primitive arithmetic operations . As a rule, each CPU has its own instruction set architecture (ISA¹).
- **Machine code** : Code that the CPU directly processes. Each instruction is usually encoded by several bytes.
- **Assembly language** : Mnemonic code and some extensions like macros that are intended to make a programmer's life easier.
- **CPU register** : Each CPU has a fixed set of general purpose registers (GPR²). ≈ 8 in x86, ≈ 16 in x86-64, ≈ 16 in ARM. The easiest way to understand a register is to think of it as an untyped temporary variable . Imagine if you were working with a high-level PL³ and could only use eight 32-bit (or 64-bit) variables . Yet a lot can be done using just these!

One might wonder why there needs to be a difference between machine code and a PL. The answer lies in the fact that humans and CPUs are not alike— it is much easier for humans to use a high-level PL like C/C++, Java, Python, etc., but it is easier for a CPU to use a much lower level of abstraction. Perhaps it would be possible to invent a CPU that can execute high-level PL code, but it would be many times more complex than the CPUs we know of today. In a similar fashion, it is very inconvenient for humans to write in assembly language, due to it being so low-level and difficult to write in without making a huge number of annoying

¹Instruction Set Architecture

²General Purpose Registers

³Programming language

mistakes. The program that converts the high-level PL code into assembly is called a *compiler*.

The simplest Function

The simplest possible function is arguably one that simply returns a constant value: Here it is:

```
Listing 2.1: C/C++ Code
```

Lets compile it!

2.1 x86

Here's what both the optimizing GCC and MSVC compilers produce on the x86 platform:

```
Listing 2.2: Optimizing GCC/MSVC (assembly output)
```

t:				
	mov	eax,	123	
	ret			

There are just two instructions: the first places the value 123 into the EAX register, which is used by convention for storing the return value and the second one is RET, which returns execution to the caller. The caller will take the result from the EAX register.

It is worth noting that MOV is a misleading name for the instruction in both x86 and ARM ISAs. The data is not in fact *moved*, but *copied*.

Hello, world!

Let's use the famous example from the book "The C programming Language" [Ker88]:

```
#include <stdio.h>
int main()
{
    printf("hello, world\n");
    return 0;
}
```

3.1 x86

3.1.1 MSVC

Let's compile it in MSVC 2010:

cl 1.cpp /Fa1.asm

(/Fa option instructs the compiler to generate assembly listing file)

```
Listing 3.1: MSVC 2010
```

```
CONST SEGMENT

$SG3830 DB 'hello, world', OAH, OOH

CONST ENDS

PUBLIC _main

EXTRN _printf:PROC

; Function compile flags: /Odtp
```

_TEXT _main	SEGMENT PROC	
	push	ebp
	mov	ebp, esp
	push	OFFSET \$SG3830
	call	_printf
	add	esp, 4
	xor	eax, eax
	рор	ebp
	ret	0
_main	ENDP	
_TEXT	ENDS	

The compiler generated the file, 1.obj, which is to be linked into 1.exe. In our case, the file contains two segments: CONST (for data constants) and _TEXT (for code).

The string hello, world in C/C++ has type const char[] [Str13, p176, 7.3.2], but it does not have its own name. The compiler needs to deal with the string somehow so it defines the internal name \$SG3830 for it.

That is why the example may be rewritten as follows:

```
#include <stdio.h>
const char $SG3830[]="hello, world\n";
int main()
{
    printf($SG3830);
    return 0;
}
```

Let's go back to the assembly listing. As we can see, the string is terminated by a zero byte, which is standard for C/C++ strings. More about C strings: 25.1.1 on page 167.

In the code segment, _TEXT, there is only one function so far: main(). The function main() starts with prologue code and ends with epilogue code (like almost any function)¹.

After the function prologue we see the call to the printf() function: CALL _printf. Before the call the string address (or a pointer to it) containing our greeting is placed on the stack with the help of the PUSH instruction.

When the printf() function returns the control to the main() function, the string address (or a pointer to it) is still on the stack. Since we do not need it

¹You can read more about it in the section about function prologues and epilogues (4 on page 11).

anymore, the stack pointer (the ESP register) needs to be corrected.

ADD ESP, 4 means add 4 to the ESP register value. Why 4? Since this is a 32-bit program, we need exactly 4 bytes for address passing through the stack. If it was x64 code we would need 8 bytes. ADD ESP, 4 is effectively equivalent to POP register but without using any register².

For the same purpose, some compilers (like the Intel C++ Compiler) may emit POP ECX instead of ADD (e.g., such a pattern can be observed in the Oracle RDBMS code as it is compiled with the Intel C++ compiler). This instruction has almost the same effect but the ECX register contents will be overwritten. The Intel C++ compiler probably uses POP ECX since this instruction's opcode is shorter than ADD ESP, x (1 byte for POP against 3 for ADD).

Here is an example of using POP instead of ADD from Oracle RDBMS:

Listing 3.2: Oracle RDBM	5 10.2 Linux (app.o file)
--------------------------	---------------------------

.text:0800029A	push	ebx
.text:0800029B	call	qksfroChild
.text:080002A0	рор	ecx

After calling printf(), the original C/C++ code contains the statement return 0 -return 0 as the result of the main() function. In the generated code this is implemented by the instruction XOR EAX, EAX. XOR is in fact just "eXclusive $OR^{"3}$ but the compilers often use it instead of MOV EAX, 0- again because it is a slightly shorter opcode (2 bytes for XOR against 5 for MOV).

Some compilers emit SUB EAX, EAX, which means *SUBtract the value in the* EAX *from the value in* EAX, which, in any case, results in zero.

The last instruction RET returns the control to the caller. Usually, this is C/C++ CRT⁴ code, which, in turn, returns control to the OS.

3.2 x86-64

3.2.1 MSVC-x86-64

Let's also try 64-bit MSVC:

Listing 3.3: MSVC 2012 x64

\$SG2989 DB 'hello, world', OAH, OOH

²CPU flags, however, are modified ³wikipedia ⁴C runtime library 1

main	PROC sub lea call xor add	rsp, 40 rcx, OFFSET FLAT:\$SG2989 printf eax, eax rsp, 40
main	ret ENDP	0

In x86-64, all registers were extended to 64-bit and now their names have an Rprefix. In order to use the stack less often (in other words, to access external memory/cache less often), there exists a popular way to pass function arguments via registers (fastcall). I.e., a part of the function arguments is passed in registers, the rest-via the stack. In Win64, 4 function arguments are passed in the RCX, RDX, R8, R9 registers. That is what we see here: a pointer to the string for printf() is now passed not in the stack, but in the RCX register.

The pointers are 64-bit now, so they are passed in the 64-bit registers (which have the R- prefix). However, for backward compatibility, it is still possible to access the 32-bit parts, using the E- prefix.

This is how the RAX/EAX/AX/AL register looks like in x86-64:

7th ^(byte number)	6th	5th	4th	3rd	2nd	1st	0th
RAX ^{x64}							
EAX							
AX						٩X	
						AH	AL

The main() function returns an *int*-typed value, which is, in C/C++, for better backward compatibility and portability, still 32-bit, so that is why the EAX register is cleared at the function end (i.e., the 32-bit part of the register) instead of RAX.

There are also 40 bytes allocated in the local stack. This is called the "shadow space", about which we are going to talk later: 8.2.1 on page 43.

3.3 Conclusion

The main difference between x86/ARM and x64/ARM64 code is that the pointer to the string is now 64-bits in length. Indeed, modern CPUs are now 64-bit due to both the reduced cost of memory and the greater demand for it by modern applications. We can add much more memory to our computers than 32-bit pointers are able to address. As such, all pointers are now 64-bit.

Function prologue and epilogue

A function prologue is a sequence of instructions at the start of a function. It often looks something like the following code fragment:

push ebp mov ebp,esp sub esp,X

What these instruction do: save the value in the EBP register, set the value of the EBP register to the value of the ESP and then allocate space on the stack for local variables.

The value in the EBP stays the same over the period of the function execution and is to be used for local variables and arguments access. For the same purpose one can use ESP, but since it changes over time this approach is not too convenient.

The function epilogue frees the allocated space in the stack, returns the value in the EBP register back to its initial state and returns the control flow to the callee:

|--|

Function prologues and epilogues are usually detected in disassemblers for function delimitation.

4.1 Recursion

Epilogues and prologues can negatively affect the recursion performance.

More about recursion in this book: **??** on page ??.

Stack

The stack is one of the most fundamental data structures in computer science¹.

Technically, it is just a block of memory in process memory along with the ESP or RSP register in x86 or x64, or the SP^2 register in ARM, as a pointer within that block.

The most frequently used stack access instructions are PUSH and POP (in both x86 and ARM Thumb-mode). PUSH subtracts from ESP/RSP/SP 4 in 32-bit mode (or 8 in 64-bit mode) and then writes the contents of its sole operand to the memory address pointed by ESP/RSP/SP.

POP is the reverse operation: retrieve the data from the memory location that SP points to, load it into the instruction operand (often a register) and then add 4 (or 8) to the stack pointer.

After stack allocation, the stack pointer points at the bottom of the stack. PUSH decreases the stack pointer and POP increases it. The bottom of the stack is actually at the beginning of the memory allocated for the stack block. It seems strange, but that's the way it is.

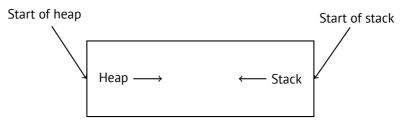

5.1 Why does the stack grow backwards?

Intuitively, we might think that the stack grows upwards, i.e. towards higher addresses, like any other data structure.

¹wikipedia.org/wiki/Call_stack

²stack pointer. SP/ESP/RSP in x86/x64. SP in ARM.

The reason that the stack grows backward is probably historical. When the computers were big and occupied a whole room, it was easy to divide memory into two parts, one for the heap and one for the stack. Of course, it was unknown how big the heap and the stack would be during program execution, so this solution was the simplest possible.

In [RT74] we can read:

The user-core part of an image is divided into three logical segments. The program text segment begins at location 0 in the virtual address space. During execution, this segment is write-protected and a single copy of it is shared among all processes executing the same program. At the first 8K byte boundary above the program text segment in the virtual address space begins a nonshared, writable data segment, the size of which may be extended by a system call. Starting at the highest address in the virtual address space is a stack segment, which automatically grows downward as the hardware's stack pointer fluctuates.

This reminds us how some students write two lecture notes using only one notebook: notes for the first lecture are written as usual, and notes for the second one are written from the end of notebook, by flipping it. Notes may meet each other somewhere in between, in case of lack of free space.

5.2 What is the stack used for?

5.2.1 Save the function's return address

x86

When calling another function with a CALL instruction, the address of the point exactly after the CALL instruction is saved to the stack and then an unconditional jump to the address in the CALL operand is executed.

: f

The CALL instruction is equivalent to a PUSH address_after_call / JMP operand instruction pair.

RET fetches a value from the stack and jumps to it - that is equivalent to a POP tmp / JMP tmp instruction pair.

Overflowing the stack is straightforward. Just run eternal recursion:

void f()
{
 f();
};

MSVC 2008 reports the problem:

...but generates the right code anyway:

?f@@YAXXZ PROC ; f ; File c:\tmp6\ss.cpp			f
	ss.chh		
; Line 2			
push	ebp		
mov	ebp, esp		
; Line 3			
call	?f@@YAXXZ	;	f
; Line 4			
рор	ebp		
ret	0		
?f@@YAXXZ ENDP		;	f

... Also if we turn on the compiler optimization (/0x option) the optimized code will not overflow the stack and will work *correctly*³ instead:

³irony here

; f

5.2.2 Passing function arguments

The most popular way to pass parameters in x86 is called "cdecl":

```
push arg3
push arg2
push arg1
call f
add esp, 12 ; 4*3=12
```

Callee functions get their arguments via the stack pointer.

Therefore, this is how the argument values are located in the stack before the execution of the f() function's very first instruction:

ESP	return address
ESP+4	argument#1, marked in IDA ⁴ as arg_0
ESP+8	argument#2, marked in IDA as arg_4
ESP+0xC	argument#3, marked in IDA as arg_8

It is worth noting that nothing obliges programmers to pass arguments through the stack. It is not a requirement. One could implement any other method without using the stack at all.

For example, it is possible to allocate a space for arguments in the heap, fill it and pass it to a function via a pointer to this block in the EAX register. This will work⁵. However, it is a convenient custom in x86 and ARM to use the stack for this purpose.

By the way, the callee function does not have any information about how many arguments were passed. C functions with a variable number of arguments (like printf()) determine their number using format string specifiers (which begin with the % symbol). If we write something like

printf("%d %d %d", 1234);

printf() will print 1234, and then two random numbers, which were lying next to it in the stack.

⁵For example, in the "The Art of Computer Programming" book by Donald Knuth, in section 1.4.1 dedicated to subroutines [Knu98, section 1.4.1], we could read that one way to supply arguments to a subroutine is simply to list them after the JMP instruction passing control to subroutine. Knuth explains that this method was particularly convenient on IBM System/360.

```
That's why it is not very important how we declare the main() function: as main(), main(int argc, char *argv[]) or main(int argc, char *argv[], char *envp[]).
```

In fact, the CRT-code is calling main() roughly as:

push envp push argv push argc call main ...

If you declare main() as main() without arguments, they are, nevertheless, still present in the stack, but are not used. If you declare main() as main(int argc, char *argv[]), you will be able to use first two arguments, and the third will remain "invisible" for your function. Even more, it is possible to declare main(int argc), and it will work.

5.2.3 Local variable storage

A function could allocate space in the stack for its local variables just by decreasing the stack pointer towards the stack bottom. Hence, it's very fast, no matter how many local variables are defined.

It is also not a requirement to store local variables in the stack. You could store local variables wherever you like, but traditionally this is how it's done.

5.2.4 x86: alloca() function

It is worth noting the alloca() function⁶.

This function works like malloc(), but allocates memory directly on the stack.

The allocated memory chunk does not need to be freed via a free() function call, since the function epilogue (4 on page 11) returns ESP back to its initial state and the allocated memory is just *dropped*.

It is worth noting how alloca() is implemented.

In simple terms, this function just shifts ESP downwards toward the stack bottom by the number of bytes you need and sets ESP as a pointer to the *allocated* block. Let's try:

 $^{^{6}}$ In MSVC, the function implementation can be found in alloca16.asm and chkstk.asm in C:\Program Files (x86)\Microsoft Visual Studio 10.0\VC\crt\src\intel

```
#ifdef
       GNUC
#include <alloca.h> // GCC
#else
#include <malloc.h> // MSVC
#endif
#include <stdio.h>
void f()
{
    char *buf=(char*)alloca (600);
#ifdef GNUC
    snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3); // GCC
#else
    _snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3); // MSVC
#endif
    puts (buf);
};
```

_snprintf() function works just like printf(), but instead of dumping the result into stdout (e.g., to terminal or console), it writes it to the buf buffer. Function puts() copies the contents of buf to stdout. Of course, these two function calls might be replaced by one printf() call, but we have to illustrate small buffer usage.

MSVC

Let's compile (MSVC 2010):

Listing 5.1: MSVC 2010

•••		
	mov call mov	eax, 600 ; 00000258H alloca_probe_16 esi, esp
	push push push push push push call	3 2 1 OFFSET \$SG2672 600 ; 00000258H esi snprintf
	push	esi

CHAPTER 5. STACK			CHAPTER 5. STACK
call	_puts		
add	esp, 28	; 000001cH	
•••			

The sole alloca() argument is passed via EAX (instead of pushing it into the stack)⁷. After the alloca() call, ESP points to the block of 600 bytes and we can use it as memory for the buf array.

5.2.5 (Windows) SEH

SEH¹⁰ records are also stored on the stack (if they are present)..

5.2.6 Buffer overflow protection

More about it here (16.2 on page 95).

5.2.7 Automatic deallocation of data in stack

Perhaps, the reason for storing local variables and SEH records in the stack is that they are freed automatically upon function exit, using just one instruction to correct the stack pointer (it is often ADD). Function arguments, as we could say, are also deallocated automatically at the end of function. In contrast, everything stored in the *heap* must be deallocated explicitly.

5.3 A typical stack layout

A typical stack layout in a 32-bit environment at the start of a function, before the first instruction execution looks like this:

⁷It is because alloca() is rather a compiler intrinsic than a normal function.

One of the reasons we need a separate function instead of just a couple of instructions in the code, is because the $MSVC^8$ alloca() implementation also has code which reads from the memory just allocated, in order to let the OS map physical memory to this VM^9 region.

¹⁰Structured Exception Handling

ESP-0xC	local variable #2, marked in IDA as var_8	
ESP-8	local variable #1, marked in IDA as var_4	
ESP-4	saved value of EBP	
ESP	return address	
ESP+4	argument#1, marked in IDA as arg_0	
ESP+8	argument#2, marked in IDA as arg_4	
ESP+0xC	argument#3, marked in IDA as arg_8	

printf() with several arguments

Now let's extend the *Hello, world!* (3 on page 7) example, replacing printf() in the main() function body with this:

```
#include <stdio.h>
int main()
{
    printf("a=%d; b=%d; c=%d", 1, 2, 3);
    return 0;
};
```

6.1 x86

6.1.1 x86: 3 arguments

MSVC

When we compile it with MSVC 2010 Express we get:

\$SG3830 DB 'a=%d; b=%d; c=%d', 00H
...
push 3

; 2

push	2
push	1
push	OFFSET \$SG3830
call	_printf
add	esp, 16
⊊ 00000010H	

Almost the same, but now we can see the printf() arguments are pushed onto the stack in reverse order. The first argument is pushed last.

By the way, variables of *int* type in 32-bit environment have 32-bit width, that is 4 bytes.

So, we have 4 arguments here. 4 * 4 = 16 —they occupy exactly 16 bytes in the stack: a 32-bit pointer to a string and 3 numbers of type *int*.

When the stack pointer (ESP register) has changed back by the ADD ESP, X instruction after a function call, often, the number of function arguments could be deduced by simply dividing X by 4.

Of course, this is specific to the *cdecl* calling convention, and only for 32-bit environment.

In certain cases where several functions return right after one another, the compiler could merge multiple "ADD ESP, X" instructions into one, after the last call:

push a1 push a2 call	
 push a1 call	
<pre> push a1 push a2 push a3 call add esp,</pre>	24
auu esp,	24

Here is a real-world example:

Listing 6.1: x86			
.text:100113E7	push	3	
.text:100113E9	call	<pre>sub_100018B0 ; takes one</pre>	
argument (3)			
.text:100113EE	call	<pre>sub_100019D0 ; takes no</pre>	
arguments at all			
.text:100113F3	call	<pre>sub_10006A90 ; takes no</pre>	
arguments at all			

CHAPTER 6. PRINTF() WITH SEVERAL ARGUMENTS		CHAPTER 6. PRINTF()	WITH SEVERAL ARGUMENTS
.text:100113F8	push	1	
.text:100113FA	call	sub_100018B0	; takes one
argument (1)			
.text:100113FF	add	esp, 8	; drops two
arguments from stack at	once		

6.1.2 x64: 8 arguments

To see how other arguments are passed via the stack, let's change our example again by increasing the number of arguments to 9 (printf() format string + 8 *int* variables):

```
#include <stdio.h>
int main()
{
    printf("a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\
    v n", 1, 2, 3, 4, 5, 6, 7, 8);
    return 0;
};
```

MSVC

As it was mentioned earlier, the first 4 arguments has to be passed through the RCX, RDX, R8, R9 registers in Win64, while all the rest-via the stack. That is exactly what we see here. However, the MOV instruction, instead of PUSH, is used for preparing the stack, so the values are stored to the stack in a straightforward manner.

Listing 6.2: MSVC 2012 x64

\$SG2923 [、、'、	DB 0aH, 00		b=%d	; c=%d;	d=%d ;	e=%d;	f=%d;	g=%d ;	h=%d∠
_	PROC sub	rsp, 8	8						
ח ח ח ח ח	mov mov mov mov mov mov	DWORD DWORD DWORD	PTR [PTR [PTR [PTR [rsp+64] rsp+56] rsp+48] rsp+40] rsp+32]	, 7 , 6 , 5				

```
edx, 1
        mov
        lea
                 rcx, OFFSET FLAT:$SG2923
        call
                 printf
         : return 0
                 eax, eax
        xor
        add
                 rsp, 88
         ret
                 0
main
        FNDP
TEXT
        ENDS
FND
```

The observant reader may ask why are 8 bytes allocated for *int* values, when 4 is enough? Yes, one has to remember: 8 bytes are allocated for any data type shorter than 64 bits. This is established for the convenience's sake: it makes it easy to calculate the address of arbitrary argument. Besides, they are all located at aligned memory addresses. It is the same in the 32-bit environments: 4 bytes are reserved for all data types.

6.2 Conclusion

Here is a rough skeleton of the function call:

Listing 6.3: x86

```
...
PUSH 3rd argument
PUSH 2nd argument
PUSH 1st argument
CALL function
; modify stack pointer (if needed)
```

Listing 6.4: x64 (MSVC)

```
MOV RCX, 1st argument
MOV RDX, 2nd argument
MOV R8, 3rd argument
MOV R9, 4th argument
...
PUSH 5th, 6th argument, etc (if needed)
CALL function
; modify stack pointer (if needed)
```

6.3 By the way

By the way, this difference between the arguments passing in x86, x64, fastcall, ARM and MIPS is a good illustration of the fact that the CPU is oblivious to how the arguments are passed to functions. It is also possible to create a hypothetical compiler able to pass arguments via a special structure without using stack at all.

The CPU is not aware of calling conventions whatsoever.

We may also recall how newcoming assembly language programmers passing arguments into other functions: usually via registers, without any explicit order, or even via global variables. Of course, it works fine.

Chapter 7

scanf()

Now let's use scanf().

7.1 Simple example

```
#include <stdio.h>
int main()
{
    int x;
    printf ("Enter X:\n");
    scanf ("%d", &x);
    printf ("You entered %d...\n", x);
    return 0;
};
```

It's not clever to use scanf() for user interactions nowadays. But we can, however, illustrate passing a pointer to a variable of type *int*.

7.1.1 About pointers

Pointers are one of the fundamental concepts in computer science. Often, passing a large array, structure or object as an argument to another function is too expensive, while passing their address is much cheaper. In addition if the callee function

needs to modify something in the large array or structure received as a parameter and return back the entire structure then the situation is close to absurd. So the simplest thing to do is to pass the address of the array or structure to the callee function, and let it change what needs to be changed.

A pointer in C/C++ is simply an address of some memory location.

In x86, the address is represented as a 32-bit number (i.e., it occupies 4 bytes), while in x86-64 it is a 64-bit number (occupying 8 bytes). By the way, that is the reason behind some people's indignation related to switching to x86-64-all pointers in the x64-architecture require twice as much space, including cache memory, which is "expensive" place.

It is possible to work with untyped pointers only, given some effort; e.g. the standard C function memcpy(), that copies a block from one memory location to another, takes 2 pointers of type void* as arguments, since it is impossible to predict the type of the data you would like to copy. Data types are not important, only the block size matters.

Pointers are also widely used when a function needs to return more than one value (we are going to get back to this later). *scanf()* is such a case. Besides the fact that the function needs to indicate how many values were successfully read, it also needs to return all these values.

In C/C++ the pointer type is only needed for compile-time type checking. Internally, in the compiled code there is no information about pointer types at all.

7.1.2 x86

MSVC

Here is what we get after compiling with MSVC 2010:

```
CONST
         SEGMENT
                  'Enter X:', 0aH, 00H
$SG3831
           DB
$SG3832
                  '%d', 00H
           DB
$SG3833
           DB
                  'You entered %d...', OaH, OOH
CONST
         ENDS
PUBLIC
          main
         scanf:PROC
EXTRN
         _printf:PROC
FXTRN
; Function compile flags: /Odtp
_TEXT
         SEGMENT
x = -4
                                 ; size = 4
         PROC
main
    push
           ebp
    mov
           ebp, esp
```

```
push
           ecx
           OFFSET $SG3831 ; 'Enter X:'
    push
    call
           printf
    add
           esp, 4
    lea
           eax, DWORD PTR x$[ebp]
    push
           eax
    push
           OFFSET $SG3832 ; '%d'
    call
           scanf
    add
           esp, 8
    mov
           ecx, DWORD PTR _x$[ebp]
    push
           ecx
           OFFSET $SG3833 ; 'You entered %d...'

x is a local variable.

According to the C/C++ standard it must be visible only in this function and not from any other external scope. Traditionally, local variables are stored on the stack. There are probably other ways to allocate them, but in x86 that is the way it is.

The goal of the instruction following the function prologue, PUSH ECX, is not to save the ECX state (notice the absence of corresponding POP ECX at the function's end).

In fact it allocates 4 bytes on the stack for storing the x variable.

x is to be accessed with the assistance of the $_x$ macro (it equals to -4) and the EBP register pointing to the current frame.

Over the span of the function's execution, EBP is pointing to the current stack frame making it possible to access local variables and function arguments via EBP+offset.

It is also possible to use ESP for the same purpose, although that is not very convenient since it changes frequently. The value of the EBP could be perceived as a *frozen state* of the value in ESP at the start of the function's execution.

Here is a typical stack frame layout in 32-bit environment:

EBP-8	local variable #2, marked in IDA as var_8
EBP-4	local variable #1, marked in IDA as var_4
EBP	saved value of EBP
EBP+4	return address
EBP+8	argument#1, marked in IDA as arg_0
EBP+0xC	argument#2, marked in IDA as arg_4
EBP+0x10	argument#3, marked in IDA as arg_8

The scanf() function in our example has two arguments.

The first one is a pointer to the string containing %d and the second is the address of the x variable.

First, the x variable's address is loaded into the EAX register by the lea eax, DWORD PTR _x[ebp] instruction

We could say that in this case LEA simply stores the sum of the EBP register value and the $_x$ macro in the EAX register.

This is the same as lea eax, [ebp-4].

So, 4 is being subtracted from the EBP register value and the result is loaded in the EAX register. Next the EAX register value is pushed into the stack and scanf() is being called.

printf() is being called after that with its first argument -a pointer to the string: You entered %d...

The second argument is prepared with: mov ecx, [ebp-4]. The instruction stores the x variable value and not its address, in the ECX register.

Next the value in the ECX is stored on the stack and the last printf() is being called.

By the way

By the way, this simple example is a demonstration of the fact that compiler translates list of expressions in C/C++-block into sequential list of instructions. There are nothing between expressions in C/C++, and so in resulting machine code, there are nothing between, control flow slips from one expression to the next one.

7.1.3 x64

The picture here is similar with the difference that the registers, rather than the stack, are used for arguments passing.

MSVC

```
Listing 7.1: MSVC 2012 x64
```

\$SG1289 \$SG1291	DB DB	
_TEXT x\$ = 32	SEGMENT	
main \$LN3:		
	call	<pre>printf rdx, QWORD PTR x\$[rsp] rcx, OFFSET FLAT:\$SG1291 ; '%d' scanf edx, DWORD PTR x\$[rsp] rcx, OFFSET FLAT:\$SG1292 ; 'You entered %d'</pre>
main _TEXT	add ret	n O eax, eax rsp, 56 O

7.2 Global variables

What if the x variable from the previous example was not local but a global one? Then it would have been accessible from any point, not only from the function body. Global variables are considered anti-pattern, but for the sake of the experiment, we could do this.

```
#include <stdio.h>
// now x is global variable
int x;
int main()
{
```

};

```
printf ("Enter X:\n");
scanf ("%d", &x);
printf ("You entered %d...\n", x);
return 0;
```

7.2.1 MSVC: x86

_DATA	SEGMENT	
COMM	_x:DWORD	
\$SG2456	DB	'Enter X:', OaH, OOH

рор	•	
ret	0	
_main		
_TEXT	ENDS	

In this case the x variable is defined in the _DATA segment and no memory is allocated in the local stack. It is accessed directly, not through the stack. Uninitialized global variables take no space in the executable file (indeed, why one needs to allocate space for variables initially set to zero?), but when someone accesses their address, the OS will allocate a block of zeroes there¹.

Now let's explicitly assign a value to the variable:

```
int x=10; // default value
```

We got:

_DATA SEGMENT _x DD 0aH

Here we see a value 0xA of DWORD type (DD stands for DWORD = 32 bit) for this variable.

If you open the compiled .exe in IDA, you can see the *x* variable placed at the beginning of the _DATA segment, and after it you can see text strings.

If you open the compiled .exe from the previous example in IDA, where the value of x was not set, you would see something like this:

.data:0040FA80 _x	dd ?	; DATA 2
<pre></pre>		; main∠
·		,
.data:0040FA84 dword_40FA84	dd ?	; DATA 🖌

<pre>sbh_free_block+2CA</pre>		
	dd ?	; DATA 🖌
<pre></pre>		• 2
<pre>\u00ed classes under \u00ed classes under \u00</pre>		; 2
.data:0040FA94 dword_40FA94	dd ?	; DATA 🖌
<pre>└→ XREF:sbh_free_block+</pre>	2FE	

¹That is how a VM behaves

_x is marked with ? with the rest of the variables that do not need to be initialized. This implies that after loading the .exe to the memory, a space for all these variables is to be allocated and filled with zeroes [ISO07, 6.7.8p10]. But in the .exe file these uninitialized variables do not occupy anything. This is convenient for large arrays, for example.

        ENDS
```

The code is almost the same as in x86. Please note that the address of the x variable is passed to scanf() using a LEA instruction, while the variable's value is passed to the second printf() using a MOV instruction. DWORD PTR is a part of the assembly language (no relation to the machine code), indicating that the variable data size is 32-bit and the MOV instruction has to be encoded accordingly.

7.3 scanf() result checking

As was noted before, it is slightly old-fashioned to use scanf() today. But if we have to, we need to at least check if scanf() finishes correctly without an error.

By standard, the scanf()² function returns the number of fields it has successfully read.

In our case, if everything goes fine and the user enters a number scanf() returns 1, or in case of error (or EOF^3) – 0.

Let's add some C code to check the scanf() return value and print error message in case of an error.

This works as expected:

```
C:\...>ex3.exe
Enter X:
123
You entered 123...
C:\...>ex3.exe
Enter X:
ouch
What you entered? Huh?
```

7.3.1 MSVC: x86

Here is what we get in the assembly output (MSVC 2010):

```
<sup>2</sup>scanf, wscanf: MSDN
<sup>3</sup>End of file
```

lea push	eax, DWORD PTR _x\$[ebp] eax
, push	OFFSET \$SG3833 ; '%d', 00H
call	=
add	esp, 8
cmp	eax, 1
jne	SHORT \$LN2@main
mov	ecx, DWORD PTR _x\$[ebp]
push	ecx
push	OFFSET \$SG3834 ; 'You entered %d', OaH, OOH
call	_printf
add	esp, 8
jmp	SHORT \$LN1@main
\$LN2@main:	
push	OFFSET \$SG3836 ; 'What you entered? Huh?', OaH,∠
 ↓ 00Н 	
call	_printf
add	esp, 4
\$LN1@main:	• •
xor	eax, eax

The caller function (main()) needs the callee function (scanf()) result, so the callee returns it in the EAX register.

We check it with the help of the instruction CMP EAX, 1 (*CoMPare*). In other words, we compare the value in the EAX register with 1.

A JNE conditional jump follows the CMP instruction. JNE stands for *Jump if Not Equal*.

So, if the value in the EAX register is not equal to 1, the CPU will pass the execution to the address mentioned in the JNE operand, in our case \$LN2@main. Passing the control to this address results in the CPU executing printf() with the argument What you entered? Huh?. But if everything is fine, the conditional jump is not be be taken, and another printf() call is to be executed, with two arguments: 'You entered %d...' and the value of x.

Since in this case the second printf() has not to be executed, there is a JMP preceding it (unconditional jump). It passes the control to the point after the second printf() and just before the XOR EAX, EAX instruction, which implements return 0.

So, it could be said that comparing a value with another is *usually* implemented by CMP/Jcc instruction pair, where *cc* is *condition code*. CMP compares two values and sets processor flags⁴. Jcc checks those flags and decides to either pass the control to the specified address or not.

⁴x86 flags, see also: wikipedia.

This could sound paradoxical, but the CMP instruction is in fact SUB (subtract). All arithmetic instructions set processor flags, not just CMP. If we compare 1 and 1, 1 - 1 is 0 so the ZF flag would be set (meaning that the last result was 0). In no other circumstances ZF can be set, except when the operands are equal. JNE checks only the ZF flag and jumps only if it is not set. JNE is in fact a synonym for JNZ (*Jump if Not Zero*). Assembler translates both JNE and JNZ instructions into the same opcode. So, the CMP instruction can be replaced with a SUB instruction and almost everything will be fine, with the difference that SUB alters the value of the first operand. CMP is *SUB without saving the result, but affecting flags*.

7.3.2 MSVC: x86 + Hiew

This can also be used as a simple example of executable file patching. We may try to patch the executable so the program would always print the input, no matter what we enter.

Assuming that the executable is compiled against external MSVCR*.DLL (i.e., with /MD option)⁵, we see the main() function at the beginning of the .text section. Let's open the executable in Hiew and find the beginning of the .text section (Enter, F8, F6, Enter, Enter).

We can see this:

Hiew: ex3.exe		×

00000448: 83C404	add	esp,4
0000044B: 33C0	xor	eax,eax
0000044D: 8BE5	mov	esp,ebp
0000044F: 5D	рор	ebp
00000450: C3		

Figure 7.2: Hiew: replacing JNZ with two NOPs

Then press F9 (update). Now the executable is saved to the disk. It will behave as we wanted.

Two NOPs are probably not the most æsthetic approach. Another way to patch this instruction is to write just 0 to the second opcode byte (jump offset), so that JNZ will always jump to the next instruction.

We could also do the opposite: replace first byte with EB while not touching the second byte (jump offset). We would get an unconditional jump that is always triggered. In this case the error message would be printed every time, no matter the input.

7.3.3 MSVC: x64

Since we work here with *int*-typed variables, which are still 32-bit in x86-64, we see how the 32-bit part of the registers (prefixed with E-) are used here as well.

⁷No OPeration

While working with pointers, however, 64-bit register parts are used, prefixed with R-.

7.4 Exercise

• http://challenges.re/53

Chapter 8

Accessing passed arguments

Now we figured out that the caller function is passing arguments to the callee via the stack. But how does the callee access them?

Listing 8.1: simple example

```
#include <stdio.h>
int f (int a, int b, int c)
{
        return a*b+c;
};
int main()
{
        printf ("%d\n", f(1, 2, 3));
        return 0;
};
```

8.1 x86

8.1.1 MSVC

Here is what we get after compilation (MSVC 2010 Express):

Listing 8.2: MSVC 2010 Express

_TEXT	SEGMENT		

_a\$ = 8		; size ∠
		; size ∠
 ⊊ = 4		,
_c\$ = 16		; size ∠
· → = 4		
_f PROC		-
push	ebp	
mov	ebp, esp	-
mo∨ imul	eax, DWORD PTR _a\$[ebp] eax, DWORD PTR _b\$[ebp]	-
add	eax, DWORD PTRD\$[ebp] eax, DWORD PTRc\$[ebp]	-
рор	ebp	
ret	0	
_f ENDP		
-		
_main PROC		
push	ebp	
mov	ebp, esp	-
push	3 ; 3rd argument	
push	2 ; 2nd argument	
push call	1 ; 1st argument _f	
add	_' esp, 12	-
push	eax	
push	OFFSET \$SG2463 ; '%d', 0aH, 00H	
call	_printf	
add	esp, 8	
; ret	turn 0	
xor	eax, eax	
рор	ebp	
ret	0	
_main ENDP		

What we see is that the main() function pushes 3 numbers onto the stack and calls f(int, int, int). Argument access inside f() is organized with the help of macros like: _a\$ = 8, in the same way as local variables, but with positive offsets (addressed with *plus*). So, we are addressing the *outer* side of the stack frame by adding the _a\$ macro to the value in the EBP register.

Then the value of *a* is stored into EAX. After IMUL instruction execution, the value in EAX is a product of the value in EAX and the content of _b. After that, ADD adds the value in _c to EAX. The value in EAX does not need to be moved: it is already where it must be. On returning to caller, it takes the EAX value and use it as an argument to printf().

8.2 x64

The story is a bit different in x86-64. Function arguments (first 4 or first 6 of them) are passed in registers i.e. the callee reads them from registers instead of reading them from the stack.

8.2.1 MSVC

Optimizing MSVC:

		Listing 8.3: Optimizing MSVC 2012 x64
\$SG2997	DB	'%d', OaH, OOH
main	PROC sub mov lea lea call lea mov call xor add ret ENDP	f rcx, OFFSET FLAT:\$SG2997 ; '%d' edx, eax printf
f	; EDX - ; R8D -	1st argument 2nd argument 3rd argument ecx, edx eax, DWORD PTR [r8+rcx] 0

As we can see, the compact function f() takes all its arguments from the registers. The LEA instruction here is used for addition, apparently the compiler considered it faster than ADD. LEA is also used in the main() function to prepare the first and third f() arguments. The compiler must have decided that this would work faster than the usual way of loading values into a register using MOV instruction.

Let's take a look at the non-optimizing MSVC output:

Listing 8.4: MSVC 2012 x64

f proc near ; shadow space: arg O = dword ptr 8 = dword ptr arg_8 10h = dword ptr 18h arg_10 ; ECX - 1st argument EDX - 2nd argument ; R8D - 3rd argument [rsp+arg_10], r8d mov mov [rsp+arg 8], edx mov [rsp+arg_0], ecx eax, [rsp+arg_0] mov eax, [rsp+arg_8] imul add eax, [rsp+arg 10] retn f endp main proc near sub rsp, 28h r8d, 3 ; 3rd argument mov edx, 2 ; 2nd argument mov mov ecx, 1 ; 1st argument call f mov edx, eax lea rcx, \$SG2931 "%d\n" call. printf : return 0 eax, eax xor add rsp, 28h retn main endp

It looks somewhat puzzling because all 3 arguments from the registers are saved to the stack for some reason. This is called "shadow space" ¹: every Win64 may (but is not required to) save all 4 register values there. This is done for two reasons: 1) it is too lavish to allocate a whole register (or even 4 registers) for an input argument, so it will be accessed via stack; 2) the debugger is always aware where to find the function arguments at a break².

So, some large functions can save their input arguments in the "shadows space" if they need to use them during execution, but some small functions (like ours) may

¹MSDN ²MSDN not do this.

It is a caller responsibility to allocate "shadow space" in the stack.

Chapter 9

More about results returning

In x86, the result of function execution is usually returned¹ in the EAX register. If it is byte type or a character (*char*), then the lowest part of register EAX (AL) is used. If a function returns a *float* number, the FPU register ST(0) is used instead.

9.1 Attempt to use the result of a function returning *void*

So, what if the main() function return value was declared of type *void* and not *int*?

The so-called startup-code is calling main() roughly as follows:

push envp push argv push argc call main push eax call exit

In other words:

exit(main(argc,argv,envp));

If you declare main() as *void*, nothing is to be returned explicitly (using the *return* statement), then something random, that was stored in the EAX register at the end

¹See also: MSDN: Return Values (C++): MSDN

of main() becomes the sole argument of the exit() function. Most likely, there will be a random value, left from your function execution, so the exit code of program is pseudorandom.

We can illustrate this fact. Please note that here the main() function has a *void* return type:

Let's compile it in Linux.

GCC 4.8.1 replaced printf() with puts(), but that's OK, since puts() returns the number of characters printed out, just like printf(). Please notice that EAX is not zeroed before main()'s end. This implies that the value of EAX at the end of main() contains what puts() has left there.

Listing 9.1: GCC 4.8.1

```
.LC0:
        .string "Hello, world!"
main:
        push
                 ebp
                 ebp, esp
        mov
                 esp, -16
        and
        sub
                 esp, 16
                 DWORD PTR [esp], OFFSET FLAT:.LCO
        mov
        call
                 puts
        leave
        ret
```

Let's write a bash script that shows the exit status:

Listing 9.2: tst.sh

#!/bin/sh
./hello_world
echo \$?

And run it:

\$ tst.sh
Hello, world!
14

14 is the number of characters printed.

9.2 What if we do not use the function result?

printf() returns the count of characters successfully output, but the result of this function is rarely used in practice. It is also possible to call a function whose essence is in returning a value, and not use it:

```
int f()
{
    // skip first 3 random values
    rand();
    rand();
    rand();
    // and use 4th
    return rand();
};
```

The result of the rand() function is left in EAX, in all four cases. But in the first 3 cases, the value in EAX is just thrown away.

Chapter 10

GOTO operator

The GOTO operator is generally considered as anti-pattern. [Dij68], Nevertheless, it can be used reasonably [Knu74], [Yur13, p. 1.3.2].

Here is a very simple example:

Here is what we have got in MSVC 2012:

Listing 10.1: MSVC 2012

\$SG2934 \$SG2936 \$SG2937	DB	'begin', OaH, OOH 'skip me!', OaH, OOH 'end', OaH, OOH
_main	PROC push mov push call add jmp	ebp ebp, esp OFFSET \$SG2934 ; 'begin' _printf esp, 4 SHORT \$exit\$3

\$exit\$3	push call add	OFFSET \$SG2936 ; 'skip me!' _printf esp, 4
+CALC+D		OFFEFT ¢CC2027 . Land
	push	OFFSET \$SG2937 ; 'end'
	call	_printf
	add	esp, 4
	xor	eax, eax
	рор	ebp
	ret	0
_main	ENDP	

The *goto* statement has been simply replaced by a JMP instruction, which has the same effect: unconditional jump to another place.

The second printf() could be executed only with human intervention, by using a debugger or by patching the code.

10.1 Dead code

The second printf() call is also called "dead code" in compiler terms. This means that the code will never be executed. So when you compile this example with optimizations, the compiler removes "dead code", leaving no trace of it:

Listing 10.2: Optimizing MSVC 2012

\$SG2981 DB \$SG2983 DB \$SG2984 DB	'begin', OaH, OOH 'skip me!', OaH, OOH 'end', OaH, OOH
_main PROC push call push	OFFSET \$SG2981 ; 'begin' _printf OFFSET \$SG2984 ; 'end'
<pre>\$exit\$4:</pre>	
call add xor ret _main ENDP	_printf esp, 8 eax, eax O

However, the compiler forgot to remove the "skip me!" string.

Chapter 11

Conditional jumps

11.1 Simple example

```
#include <stdio.h>
void f_signed (int a, int b)
{
    if (a>b)
        printf ("a>b\n");
    if (a==b)
        printf ("a==b\n");
    if (a<b)
        printf ("a<b\n");</pre>
};
void f_unsigned (unsigned int a, unsigned int b)
{
    if (a>b)
        printf ("a>b\n");
    if (a==b)
        printf ("a==b\n");
    if (a<b)
        printf ("a<b\n");</pre>
};
int main()
{
    f_signed(1, 2);
    f_unsigned(1, 2);
    return 0;
```

11.1.1 x86

x86 + MSVC

};

Here is how the f_signed() function looks like:

1	111.			NACV/C	2010
i istina	111	INON-O	ptimizing	INISVU	7010
Listing		11011 0	pennenng	11210	2010

```
a$ = 8
b$ = 12
f signed PROC
   push
          ebp
    mov
           ebp, esp
          eax, DWORD PTR _a$[ebp]
   mov
           eax, DWORD PTR _b$[ebp]
    cmp
    jle
          SHORT $LN3@f signed
   push
          OFFSET $SG737
                                ; 'a>b'
   call
           printf
    add
           esp, 4
$LN3@f_signed:
   mov
         ecx, DWORD PTR a$[ebp]
          ecx, DWORD PTR _b$[ebp]
   cmp
   jne
           SHORT $LN2@f_signed
   push
           OFFSET $SG739
                                 : 'a==b'
   call
           _printf
    add
           esp, 4
$LN2@f_signed:
           edx, DWORD PTR _a$[ebp]
    mov
         edx, DWORD PTR b$[ebp]
    cmp
          SHORT $LN4@f signed
    jge
                                 'a<b'
           OFFSET $SG741
   push
   call
           _printf
   add
           esp, 4
$LN4@f signed:
   pop
           ebp
    ret
           0
f signed ENDP
```

The first instruction, JLE, stands for *Jump if Less or Equal*. In other words, if the second operand is larger or equal to the first one, the control flow will be passed to the specified in the instruction address or label. If this condition does not trigger because the second operand is smaller than the first one, the control flow would

not be altered and the first printf() would be executed. The second check is JNE: *Jump if Not Equal*. The control flow will not change if the operands are equal.

The third check is JGE: *Jump if Greater or Equal*—jump if the first operand is larger than the second or if they are equal. So, if all three conditional jumps are triggered, none of the printf() calls would be executed whatsoever. This is impossible without special intervention.

Now let's take a look at the $f_unsigned()$ function. The $f_unsigned()$ function is the same as $f_signed()$, with the exception that the JBE and JAE instructions are used instead of JLE and JGE, as follows:

_a\$ = 8 ; size = 4	
_b\$ = 12 ; size = 4	
_f_unsigned PROC	
push ebp	
mov ebp, esp	
<pre>mov eax, DWORD PTR _a\$[ebp]</pre>	
<pre>cmp eax, DWORD PTR _b\$[ebp]</pre>	
jbe SHORT \$LN3@f_unsigned	
push OFFSET \$SG2761 ; 'a>b'	
call _printf	
add esp, 4	
<pre>\$LN3@f_unsigned:</pre>	
<pre>mov ecx, DWORD PTR _a\$[ebp]</pre>	
<pre>cmp ecx, DWORD PTR _b\$[ebp]</pre>	
jne SHORT \$LN2@f_unsigned	
push OFFSET \$SG2763 ; 'a==b'	
call _printf	
add esp, 4	
<pre>\$LN2@f_unsigned:</pre>	
<pre>mov edx, DWORD PTR _a\$[ebp]</pre>	
<pre>cmp edx, DWORD PTR _b\$[ebp]</pre>	
jae SHORT \$LN4@f_unsigned	
push OFFSET \$SG2765 ; 'a <b'< td=""><td></td></b'<>	
call _printf	
add esp, 4	
<pre>\$LN4@f_unsigned:</pre>	
pop ebp	
ret O	
_f_unsigned ENDP	

Listing 11.2: GCC

As already mentioned, the branch instructions are different: JBE–Jump if Below or Equal and JAE–Jump if Above or Equal. These instructions (JA/JAE/JB/JBE) differ from JG/JGE/JL/JLE in the fact that they work with unsigned numbers.

See also the section about signed number representations (22 on page 157). That is why if we see JG/JL in use instead of JA/JB or vice-versa, we can be almost sure that the variables are signed or unsigned, respectively.

Here is also the main() function, where there is nothing much new to us:

Listing 11.3: main()

_main	PROC	
	push	ebp
	mov	ebp, esp
	push	2
	push	1
	call	_f_signed
	add	esp, 8
	push	2
	push	1
	call	_f_unsigned
	add	esp, 8
	xor	eax, eax
	рор	ebp
	ret	0
_main	ENDP	

x86 + MSVC + Hiew

We can try to patch the executable file in a way that the f_unsigned() function would always print "a==b", no matter the input values. Here is how it looks in Hiew:

🖽 Hiew: 7_1.exe		
C:\Polygon\ollydbg\7_1.exe	☑FRO	a32 PE .00401000 Hiew 8.02 (c)SEN

Figure 11.1: Hiew: f_unsigned() function

Essentially, we need to accomplish three tasks:

- force the first jump to always trigger;
- force the second jump to never trigger;
- force the third jump to always trigger.

Thus we can direct the code flow to always pass through the second printf(), and output "a==b".

Three instructions (or bytes) has to be patched:

- The first jump becomes JMP, but the jump offset would remain the same.
- The second jump might be triggered sometimes, but in any case it will jump to the next instruction, because, we set the jump offset to 0. In these instructions the jump offset is added to the address for the next instruction. So if the offset is 0, the jump will transfer the control to the next instruction.

• The third jump we replace with JMP just as we do with the first one, so it will always trigger.

Here is the modified code:

Hiew: 7_1.exe

Figure 11.2: Hiew: let's modify the f_unsigned() function

If we miss to change any of these jumps, then several printf() calls may execute, while we want to execute only one.

11.2 Calculating absolute value

A simple function:

11.2.1 Optimizing MSVC

This is how the code is usually generated:

Listing 11.4: Optimizing MSVC 2012 x64

```
i$ = 8
my_abs
        PROC
; ECX = input
                 ecx, ecx
        test
; check for sign of input value
; skip NEG instruction if sign is positive
        jns
                 SHORT $LN2@my abs
; negate value
        neg
                 ecx
$LN2@my_abs:
; prepare result in EAX:
        mov
                 eax, ecx
        ret
                 0
my_abs
        ENDP
```

11.3 Ternary conditional operator

The ternary conditional operator in C/C++ has the following syntax:

```
expression ? expression : expression
```

Here is an example:

```
const char* f (int a)
{
     return a==10 ? "it is ten" : "it is not ten";
};
```

11.3.1 x86

Old and non-optimizing compilers generate assembly code just as if an if/else statement was used:

Listing 11.5: Non-optimizing MSVC 2008

```
$SG746 DB 'it is ten', 00H
$SG747 DB 'it is not ten', 00H
tv65 = -4 ; this will be used as a temporary variable
_a$ = 8
_f PROC
_ push ebp
```

```
mov
                ebp, esp
        push
                ecx
; compare input value with 10
                DWORD PTR a$[ebp], 10
        cmp
 jump to $LN3@f if not equal
                SHORT $LN3@f
        ine
 store pointer to the string into temporary variable:
                DWORD PTR tv65[ebp], OFFSET $SG746 ; 'it is ten∠
        mov
   61
; jump to exit
                SHORT $LN4@f
        jmp
$LN3@f:
; store pointer to the string into temporary variable:
                DWORD PTR tv65[ebp], OFFSET $SG747 ; 'it is not ∠
        mov
   🖕 ten'
$LN4@f:
 this is exit. copy pointer to the string from temporary
   variable to EAX.
                eax, DWORD PTR tv65[ebp]
        mov
        mov
                esp, ebp
                ebp
        pop
                0
        ret
_f
        ENDP
```

Listing 11.6: Optimizing MSVC 2008

```
$SG792
                 'it is ten', OOH
        DB
$SG793
        DB
                 'it is not ten', OOH
a$ = 8 ; size = 4
_f
        PROC
; compare input value with 10
                DWORD PTR _a$[esp-4], 10
        cmp
                eax, OFFSET $SG792 ; 'it is ten'
        mov
; jump to $LN4@f if equal
                SHORT $LN4@f
        je
                eax, OFFSET $SG793 ; 'it is not ten'
        mov
$LN4@f:
                0
        ret
f
        FNDP
```

Newer compilers are more concise:

Listing 11.7: Optimizing MSVC 2012 x64

\$SG1355 DB	'it is ten', OOH
\$SG1356 DB	'it is not ten', OOH

```
a^{=} 8
f
        PROC
; load pointers to the both strings
                rdx, OFFSET FLAT:$SG1355 ; 'it is ten'
        lea
        lea
                rax, OFFSET FLAT:$SG1356 ; 'it is not ten'
; compare input value with 10
                ecx, 10
        cmp
; if equal, copy value from RDX ("it is ten")
 if not, do nothing. pointer to the string "it is not ten" is
   still in RAX as for now.
                rax, rdx
        cmove
        ret
                0
f
        ENDP
```

Optimizing GCC 4.8 for x86 also uses the CMOVcc instruction, while the non-optimizing GCC 4.8 uses conditional jumps.

11.3.2 Let's rewrite it in an if/else way

```
const char* f (int a)
{
         if (a==10)
             return "it is ten";
         else
             return "it is not ten";
};
```

Interestingly, optimizing GCC 4.8 for x86 was also able to use CMOVcc in this case:

Listing 11.8: Optimizing GCC 4.8

```
.1 CO:
        .string "it is ten"
.IC1:
        .string "it is not ten"
f :
.LFB0:
; compare input value with 10
        cmp
                DWORD PTR [esp+4], 10
        mov
                edx, OFFSET FLAT:.LC1 ; "it is not ten"
                eax, OFFSET FLAT:.LC0 ; "it is ten"
        mov
; if comparison result is Not Equal, copy EDX value to EAX
; if not, do nothing
        cmovne eax, edx
        ret
```

But the optimizing MSVC 2012 is not that good (yet).

11.4 Getting minimal and maximal values

11.4.1 32-bit

Listing 11.9: Non-optimizing MSVC 2013

```
a$ = 8
b$ = 12
_my_min PROC
        push
                ebp
        mov
                ebp, esp
                eax, DWORD PTR _a$[ebp]

        ret
                0
_my_max ENDP
```

These two functions differ only in the conditional jump instruction: JGE ("Jump if Greater or Equal") is used in the first one and JLE ("Jump if Less or Equal") in the second.

There is one unneeded JMP instruction in each function, which MSVC probably left by mistake.

11.5 Conclusion

11.5.1 x86

Here's the rough skeleton of a conditional jump:

```
Listing 11.10: x86
```

```
CMP register, register/value
Jcc true ; cc=condition code
false:
... some code to be executed if comparison result is false ...
JMP exit
true:
... some code to be executed if comparison result is true ...
exit:
```

11.5.2 Branchless

If the body of a condition statement is very short, the conditional move instruction can be used: MOVcc in ARM (in ARM mode), CSEL in ARM64, CMOVcc in x86.

Chapter 12

switch()/case/default

12.1 Small number of cases

```
#include <stdio.h>
void f (int a)
{
    switch (a)
    {
        case 0: printf ("zero\n"); break;
        case 1: printf ("one\n"); break;
        case 2: printf ("two\n"); break;
        default: printf ("something unknown\n"); break;
    };
};
int main()
{
    f (2); // test
};
```

12.1.1 x86

Non-optimizing MSVC

Result (MSVC 2010):

Listing 12.1: MSVC 2010

```
tv64 = -4 ; size = 4
a$ = 8 ; size = 4
     PROC
f
   push
          ebp
   mov
         ebp, esp
   push
         ecx
   mov
         eax, DWORD PTR a$[ebp]
          DWORD PTR tv64[ebp], eax
   mov
         DWORD PTR tv64[ebp], 0
   cmp
          SHORT $LN4@f
   je
   cmp
          DWORD PTR tv64[ebp], 1
          SHORT $LN3@f
   je
   cmp
         DWORD PTR tv64[ebp], 2
          SHORT $LN2@f
   je
   jmp
          SHORT $LN1@f
$LN4@f:
          OFFSET $SG739 ; 'zero', OaH, OOH
   push
   call
          _printf
   add
          esp, 4
   jmp
          SHORT $LN7@f
$LN3@f:
          OFFSET $SG741 ; 'one', OaH, OOH
   push
   call
          printf
   add
          esp, 4
          SHORT $LN7@f
   jmp
$LN2@f:
          OFFSET $SG743 ; 'two', OaH, OOH
   push
   call _printf
   add
          esp, 4
   jmp
         SHORT $LN7@f
$LN1@f:
          OFFSET $SG745 ; 'something unknown', OaH, OOH
   push
   call
         _printf
   add
          esp, 4
$LN7@f:
   mov
          esp, ebp
          ebp
   pop
   ret
          0
f
     FNDP
```

Our function with a few cases in switch() is in fact analogous to this construction:

```
void f (int a)
{
    if (a==0)
        printf ("zero\n");
```

```
CHAPTER 12. SWITCH0/CASE/DEFAULT
```

```
else if (a==1)
    printf ("one\n");
else if (a==2)
    printf ("two\n");
else
    printf ("something unknown\n");
};
```

If we work with switch() with a few cases it is impossible to be sure if it was a real switch() in the source code, or just a pack of if() statements. This implies that switch() is like syntactic sugar for a large number of nested if()s.

There is nothing especially new to us in the generated code, with the exception of the compiler moving input variable a to a temporary local variable $tv64^{1}$.

If we compile this in GCC 4.4.1, we'll get almost the same result, even with maximal optimization turned on (-03 option).

Optimizing MSVC

Now let's turn on optimization in MSVC (/Ox): cl 1.c /Fa1.asm /Ox

```
_a$ = 8 ; size = 4
f
      PROC
           eax, DWORD PTR a$[esp-4]
    mov
    sub
           eax, 0
    je
           SHORT $LN4@f
    sub
          eax, 1
           SHORT $LN3@f
    ie
    sub
           eax, 1
    ie
           SHORT $LN2@f
           DWORD PTR a$[esp-4], OFFSET $SG791 ; 'something ∠
    mov
    └> unknown', OaH, OOH
    jmp
           _printf
$LN2@f:
           DWORD PTR _a$[esp-4], OFFSET $SG789 ; 'two', OaH, OO ∠
    mov

    ⊢ H

    jmp
           printf
$LN3@f:
    mov
           DWORD PTR a$[esp-4], OFFSET $SG787 ; 'one', OaH, OO∠
    \subset H
           printf
    jmp
$LN4@f:
```

```
Listing 12.2: MSVC
```

 $^{^1\}mbox{Local}$ variables in stack are prefixed with tv-that's how MSVC names internal variables for its needs

Here we can see some dirty hacks.

First: the value of *a* is placed in EAX and 0 is subtracted from it. Sounds absurd, but it is done to check if the value in EAX was 0. If yes, the ZF flag is to be set (e.g. subtracting from 0 is 0) and the first conditional jump JE (*Jump if Equal* or synonym JZ –*Jump if Zero*) is to be triggered and control flow is to be passed to the \$LN4@f label, where the 'zero' message is being printed. If the first jump doesn't get triggered, 1 is subtracted from the input value and if at some stage the result is 0, the corresponding jump is to be triggered.

And if no jump gets triggered at all, the control flow passes to printf() with string argument 'something unknown'.

Second: we see something unusual for us: a string pointer is placed into the *a* variable, and then printf() is called not via CALL, but via JMP. There is a simple explanation for that: the caller pushes a value to the stack and calls our function via CALL. CALL itself pushes the return address (RA^2) to the stack and does an unconditional jump to our function address. Our function at any point of execution (since it do not contain any instruction that moves the stack pointer) has the following stack layout:

- ESP-points to RA
- ESP+4-points to the *a* variable

On the other side, when we need to call printf() here we need exactly the same stack layout, except for the first printf() argument, which needs to point to the string. And that is what our code does.

It replaces the function's first argument with the address of the string and jumps to printf(), as if we didn't call our function f(), but directly printf(). printf() prints a string to stdout and then executes the RET instruction, which POPs RA from the stack and control flow is returned not to f() but rather to f()'s callee, bypassing the end of the f() function.

All this is possible because printf() is called right at the end of the f() function in all cases. In some way, it is similar to the longjmp()³ function. And of course, it is all done for the sake of speed.

²Return Address

³wikipedia

12.1.2 Conclusion

A *switch()* with few cases is indistinguishable from an *if/else* construction, for example: listing.12.1.1.

12.2 A lot of cases

If a switch() statement contains a lot of cases, it is not very convenient for the compiler to emit too large code with a lot JE/JNE instructions.

```
#include <stdio.h>
void f (int a)
{
    switch (a)
    {
    case 0: printf ("zero\n"); break;
    case 1: printf ("one\n"); break;
    case 2: printf ("two\n"); break;
    case 3: printf ("three\n"); break;
    case 4: printf ("four\n"); break;
    default: printf ("something unknown\n"); break;
    };
};
int main()
{
    f (2); // test
};
```

12.2.1 x86

Non-optimizing MSVC

We get (MSVC 2010):

Listing 12.3: MSVC 2010

push mov cmp ja mov jmp	ecx eax, DWORD PTR _a\$[ebp] DWORD PTR tv64[ebp], eax DWORD PTR tv64[ebp], 4 SHORT \$LN1@f ecx, DWORD PTR tv64[ebp] DWORD PTR \$LN11@f[ecx*4]
\$LN6@f: push call add jmp \$LN5@f: push	OFFSET \$SG739 ; 'zero', OaH, OOH _printf esp, 4 SHORT \$LN9@f OFFSET \$SG741 ; 'one', OaH, OOH
call add jmp \$LN4@f:	_printf esp, 4 SHORT \$LN9@f
push call add jmp \$LN3@f:	OFFSET \$SG743 ; 'two', OaH, OOH _printf esp, 4 SHORT \$LN9@f
push call add jmp \$LN2@f:	OFFSET \$SG745 ; 'three', OaH, OOH _printf esp, 4 SHORT \$LN9@f
push call add jmp \$LN1@f:	OFFSET \$SG747 ; 'four', OaH, OOH _printf esp, 4 SHORT \$LN9@f
push call add \$LN9@f:	_printf esp, 4
mov pop ret npad \$LN11@f:	esp, ebp ebp 0 2 ; align next label
DD DD DD DD DD	\$LN6@f ; 0 \$LN5@f ; 1 \$LN4@f ; 2 \$LN3@f ; 3 \$LN2@f ; 4

What we see here is a set of printf() calls with various arguments. All they have not only addresses in the memory of the process, but also internal symbolic labels assigned by the compiler. All these labels are also mentioned in the \$LN11@f internal table.

At the function start, if a is greater than 4, control flow is passed to label LN1@f, where printf() with argument 'something unknown' is called.

But if the value of *a* is less or equals to 4, then it gets multiplied by 4 and added with the LN11@f table address. That is how an address inside the table is constructed, pointing exactly to the element we need. For example, let's say *a* is equal to 2. 2 * 4 = 8 (all table elements are addresses in a 32-bit process and that is why all elements are 4 bytes wide). The address of the LN11@f table + 8 is the table element where the LN4@f label is stored. JMP fetches the LN4@f address from the table and jumps to it.

This table is sometimes called *jumptable* or *branch table*⁴.

Then the corresponding printf() is called with argument 'two'. Literally, the jmp DWORD PTR \$LN11@f[ecx*4] instruction implies *jump to the DWORD that is stored at address* \$LN11@f + ecx * 4.

is assembly language macro that aligning the next label so that it is to be stored at an address aligned on a 4 byte (or 16 byte) boundary. This is very suitable for the processor since it is able to fetch 32-bit values from memory through the memory bus, cache memory, etc, in a more effective way if it is aligned.

Non-optimizing GCC

Let's see what GCC 4.4.1 generates:

Listing 12.4: GCC 4.4.1

```
public f
f proc near ; CODE XREF: main+10
var_18 = dword ptr -18h
arg_0 = dword ptr 8
push ebp
mov ebp, esp
sub esp, 18h
cmp [ebp+arg_0], 4
```

⁴The whole method was once called *computed GOTO* in early versions of FORTRAN: wikipedia. Not quite relevant these days, but what a term!

```
short loc 8048444
       ja
      mov
               eax, [ebp+arg_0]
       shl
              eax, 2
              eax, ds:off 804855C[eax]
      mov
       jmp
              eax
loc 80483FE: ; DATA XREF: .rodata:off 804855C
              [esp+18h+var_18], offset aZero ; "zero"
      mov
       call
             _puts
       ami
              short locret 8048450
loc_804840C: ; DATA XREF: .rodata:08048560

       jmp
loc_804841A: ; DATA XREF: .rodata:08048564
              [esp+18h+var 18], offset aTwo : "two"
      mov
       call
              _puts
       jmp
              short locret 8048450
loc_8048428: ; DATA XREF: .rodata:08048568
      mov
              [esp+18h+var_18], offset aThree ; "three"
       call
              _puts
              short locret 8048450
       jmp
loc_8048436: ; DATA XREF: .rodata:0804856C
              [esp+18h+var 18], offset aFour ; "four"
      mov
       call
              puts
              short locret 8048450
       jmp
loc_8048444: ; CODE XREF: f+A
       mov
               [esp+18h+var 18], offset aSomethingUnkno ; "∠
   └→ something unknown"
       call
              _puts
locret 8048450: ; CODE XREF: f+26
                ; f+34...
       leave
       retn
f
       endp
off 804855C dd offset loc 80483FE ; DATA XREF: f+12
            dd offset loc 804840C
            dd offset loc 804841A
            dd offset loc 8048428
            dd offset loc_8048436
```

It is almost the same, with a little nuance: argument \arg_0 is multiplied by 4 by shifting it to left by 2 bits (it is almost the same as multiplication by 4) (15.2.1 on page 92). Then the address of the label is taken from the off_804855C array, stored in EAX, and then JMP EAX does the actual jump.

12.2.2 Conclusion

Rough skeleton of switch():

Listing 12.5: x86

```
MOV REG, input
CMP REG, 4 ; maximal number of cases
JA default
SHL REG, 2 ; find element in table. shift for 3 bits in x64.
MOV REG, jump table[REG]
JMP REG
case1:
    ; do something
    JMP exit
case2:
    ; do something
    JMP exit
case3:
    ; do something
    JMP exit
case4:
    ; do something
    JMP exit
case5:
    ; do something
    JMP exit
default:
    . . .
exit:
    . . . .
jump table dd case1
           dd case2
           dd case3
           dd case4
           dd case5
```

The jump to the address in the jump table may also be implemented using this instruction: JMP jump_table[REG*4]. Or JMP jump_table[REG*8] in x64.

A *jumptable* is just array of pointers, like the one described later: 16.4 on page 102.

12.3 When there are several *case* statements in one block

Here is a very widespread construction: several *case* statements for a single block:

```
#include <stdio.h>
void f(int a)
{
        switch (a)
        {
        case 1:
        case 2:
        case 7:
        case 10:
                 printf ("1, 2, 7, 10\n");
                 break:
        case 3:
        case 4:
        case 5:
        case 6:
                 printf ("3, 4, 5\n");
                 break;
        case 8:
        case 9:
        case 20:
        case 21:
                 printf ("8, 9, 21\n");
                 break;
        case 22:
                 printf ("22\n");
                 break;
        default:
                 printf ("default\n");
                 break:
        };
};
```

```
CHAPTER 12. SWITCH()/CASE/DEFAULT
```

```
int main()
{
    f(4);
};
```

It's too wasteful to generate a block for each possible case, so what is usually done is to generate each block plus some kind of dispatcher.

59	DB	3 ; a=22
60	_f ENDP	

We see two tables here: the first table (\$LN10@f) is an index table, and the second one (\$LN11@f) is an array of pointers to blocks.

First, the input value is used as an index in the index table (line 13).

Here is a short legend for the values in the table: 0 is the first *case* block (for values 1, 2, 7, 10), 1 is the second one (for values 3, 4, 5), 2 is the third one (for values 8, 9, 21), 3 is the fourth one (for value 22), 4 is for the default block.

There we get an index for the second table of code pointers and we jump to it (line 14).

What is also worth noting is that there is no case for input value 0. That's why we see the DEC instruction at line 10, and the table starts at a = 1, because there is no need to allocate a table element for a = 0.

This is a very widespread pattern.

So why is this economical? Why isn't it possible to make it as before (12.2.1 on page 69), just with one table consisting of block pointers? The reason is that the elements in index table are 8-bit, hence it's all more compact.

12.4 Fall-through

Another very popular usage of switch() is the fall-through. Here is a small example:

```
#define R 1
1
   #define W 2
2
3
    #define RW 3
4
5
    void f(int type)
6
    {
7
             int read=0, write=0;
8
9
             switch (type)
10
             ł
11
             case RW:
12
                      read=1;
13
             case W:
                      write=1:
14
15
                      break;
16
             case R:
17
                      read=1:
                      break;
18
19
             default:
20
                      break;
21
             };
22
             printf ("read=%d, write=%d\n", read, write);
23
    };
```

If type = 1 (R), read is to be set to 1, if type = 2 (W), write is to be set to 2. In case of type = 3 (RW), both read and write is to be set to 1.

The code at line 14 is executed in two cases: if type = RW or if type = W. There is no "break" for "case RW"x and that's OK.

12.4.1 MSVC x86

	Listing 12.7: MSVC 2012					
\$SG1305 DB	'read=%d, write=%d', OaH, OOH					

```
write\$ = -12
                 : size = 4
read$ = -8
                 ; size = 4
tv64 = -4
                 size = 4
_type = 8
                 ; size = 4
_f
        PROC
        push
                ebp
        mov
                ebp, esp
        sub
                esp, 12
                DWORD PTR _read$[ebp], 0
        mov
        mov
                DWORD PTR _write$[ebp], 0
        mov
                eax, DWORD PTR type$[ebp]
        mov
                DWORD PTR tv64[ebp], eax
                DWORD PTR tv64[ebp], 1 ; R
        cmp
                SHORT $LN2@f
        je
                DWORD PTR tv64[ebp], 2 ; W
        cmp
                SHORT $LN3@f
        je
                DWORD PTR tv64[ebp], 3 ; RW
        CMD
        ie
                SHORT $LN4@f
        jmp
                SHORT $LN5@f
$LN4@f:
       ; case RW:
                DWORD PTR _read$[ebp], 1
        mov
$LN3@f:
       : case W:
        mov
                DWORD PTR write$[ebp], 1
                SHORT $LN5@f
        jmp
$LN2@f:
       ; case R:
        mov
                DWORD PTR _read$[ebp], 1
$LN5@f:
       : default
                ecx, DWORD PTR _write$[ebp]
        mov
        push
                ecx
                edx, DWORD PTR read$[ebp]
        mov
        push
                edx
                OFFSET $SG1305 ; 'read=%d, write=%d'
        push
                _printf
        call
        add
                esp, 12
                esp, ebp
        mov
                ebp
        pop
        ret
                0
f
        FNDP
```

The code mostly resembles what is in the source. There are no jumps between labels LN4@f and LN3@f: so when code flow is at LN4@f, *read* is first set to 1, then *write*. This is why it's called fall-through: code flow falls through one piece of code (setting *read*) to another (setting *write*). If type = W, we land at LN3@f, so no code setting *read* to 1 is executed.

Chapter 13

Loops

13.1 Simple example

13.1.1 x86

There is a special LOOP instruction in x86 instruction set for checking the value in register ECX and if it is not 0, to decrement ECX and pass control flow to the label in the LOOP operand. Probably this instruction is not very convenient, and there are no any modern compilers which emit it automatically. So, if you see this instruction somewhere in code, it is most likely that this is a manually written piece of assembly code.

In C/C++ loops are usually constructed using for(), while() or do/while()
statements.

Let's start with for ().

This statement defines loop initialization (set loop counter to initial value), loop condition (is the counter bigger than a limit?), what is done at each iteration (increment/decrement) and of course loop body.

```
for (initialization; condition; at each iteration)
{
    loop_body;
}
```

The generated code is consisting of four parts as well.

Let's start with a simple example:

CHAPTER 13. LOOPS

```
#include <stdio.h>
void printing_function(int i)
{
          printf ("f(%d)\n", i);
};
int main()
{
          int i;
          for (i=2; i<10; i++)
                printing_function(i);
          return 0;
};</pre>
```

Result (MSVC 2010):

Listing 13.1: MSVC 2010

```
i$ = -4
         PROC
main
   push
           ebp
   mov
           ebp, esp
   push
           ecx
   mov
           DWORD PTR i$[ebp], 2 ; loop initialization
    jmp
           SHORT $LN3@main
$LN2@main:
           eax, DWORD PTR _i$[ebp] ; here is what we do after
    mov
   each iteration:
                                    ; add 1 to (i) value
   add
           eax, 1
    mov
           DWORD PTR i$[ebp], eax
$LN3@main:
           DWORD PTR _i$[ebp], 10 ; this condition is checked
   cmp
   *before* each iteration
           SHORT $LN1@main
                                    ; if (i) is biggest or equals
   jge
   to 10, lets finish loop'
           ecx, DWORD PTR i$[ebp] ; loop body:
   mov
   call printing function(i)
   push
           ecx
    call
           printing function
    add
           esp, 4
           SHORT $LN2@main
                                    ; jump to loop begin
    jmp
                                    ; loop end
$LN1@main:
   xor
           eax, eax
    mov
           esp, ebp
           ebp
    pop
```

CHAPTER 13. LOOPS

ret O main ENDP

As we see, nothing special.

_main	PROC
push	esi
mov	esi, 2
\$LL3@mair	1:
push	esi
call	_printing_function
inc	esi
add	esp, 4
cmp	esi, 10 ; 000000aH
jl	SHORT \$LL3@main
xor	eax, eax
рор	esi
ret	0
_main	ENDP

What happens here is that space for the i variable is not allocated in the local stack anymore, but uses an individual register for it, ESI. This is possible in such small functions where there aren't many local variables.

One very important thing is that the f() function must not change the value in ESI. Our compiler is sure here. And if the compiler decides to use the ESI register in f() too, its value would have to be saved at the function's prologue and restored at the function's epilogue, almost like in our listing: please note PUSH ESI/POP ESI at the function start and end.

13.1.2 One more thing

In the generated code we can see: after initializing i, the body of the loop is not to be executed, as the condition for i is checked first, and only after that loop body can be executed. And that is correct. Because, if the loop condition is not met at the beginning, the body of the loop must not be executed. This is possible in the following case:

If *total_entries_to_process* is 0, the body of the loo must not be executed at all. This is why the condition checked before the execution.

However, an optimizing compiler may swap the condition check and loop body, if it sure that the situation described here is not possible (like in the case of our very simple example and Keil, Xcode (LLVM), MSVC in optimization mode).

13.2 Memory blocks copying routine

Real-world memory copy routines may copy 4 or 8 bytes at each iteration, use SIMD¹, vectorization, etc. But for the sake of simplicity, this example is the simplest possible.

13.2.1 Straight-forward implementation

Listing 13.3: GCC 4.9 x64 optimized for size (-Os)

```
my memcpy:
 RDI = destination address
 RSI = source address
; RDX = size of block
 initialize counter (i) at 0
                eax, eax
        xor
.L2:
; all bytes copied? exit then:
                rax, rdx
        cmp
                 .15
        je
 load byte at RSI+i:
        mov
                cl, BYTE PTR [rsi+rax]
; store byte at RDI+i:
        mov
                BYTE PTR [rdi+rax], cl
        inc
                rax ; i++
                 .12
        jmp
.L5:
```

¹Single instruction, multiple data

ret

13.3 Conclusion

Rough skeleton of loop from 2 to 9 inclusive:

```
Listing 13.4: x86
```

```
mov [counter], 2 ; initialization
jmp check
body:
  ; loop body
  ; do something here
  ; use counter variable in local stack
  add [counter], 1 ; increment
check:
    cmp [counter], 9
    jle body
```

The increment operation may be represented as 3 instructions in non-optimized code:

Listing 13.5: x86

```
MOV [counter], 2 ; initialization
JMP check
body:
  ; loop body
  ; do something here
  ; use counter variable in local stack
  MOV REG, [counter] ; increment
  INC REG
   MOV [counter], REG
check:
   CMP [counter], 9
   JLE body
```

If the body of the loop is short, a whole register can be dedicated to the counter variable:

Listing 13.6: x86

```
MOV EBX, 2 ; initialization
JMP check
body:
; loop body
```

```
; do something here
; use counter in EBX, but do not modify it!
INC EBX ; increment
check:
CMP EBX, 9
JLE body
```

Some parts of the loop may be generated by compiler in different order:

Listing 13.7: x86

```
MOV [counter], 2 ; initialization
JMP label_check
label_increment:
   ADD [counter], 1 ; increment
label_check:
   CMP [counter], 10
   JGE exit
   ; loop body
   ; do something here
   ; use counter variable in local stack
   JMP label_increment
exit:
```

Usually the condition is checked *before* loop body, but the compiler may rearrange it in a way that the condition is checked *after* loop body. This is done when the compiler is sure that the condition is always *true* on the first iteration, so the body of the loop is to be executed at least once:

```
Listing 13.8: x86
```

```
MOV REG, 2 ; initialization
body:
  ; loop body
  ; do something here
  ; use counter in REG, but do not modify it!
  INC REG ; increment
  CMP REG, 10
  JL body
```

Using the LOOP instruction. This is rare, compilers are not using it. When you see it, it's a sign that this piece of code is hand-written:

Listing 13.9: x86

; count from 10 to 1 MOV ECX, 10 body:

```
; loop body
; do something here
; use counter in ECX, but do not modify it!
LOOP body
```

Chapter 14

Simple C-strings processing

14.1 strlen()

Let's talk about loops one more time. Often, the strlen() function¹ is implemented using a while() statement. Here is how it is done in the MSVC standard libraries:

```
int my_strlen (const char * str)
{
            const char *eos = str;
            while( *eos++ ) ;
            return( eos - str - 1 );
}
int main()
{
            // test
            return my_strlen("hello!");
};
```

¹counting the characters in a string in the C language

14.1.1 x86

Non-optimizing MSVC

```
Let's compile:
```

```
eos = -4
                                 ; size = 4
str = 8
                                  : size = 4
strlen PROC
    push
            ebp
            ebp, esp
    mov
   push
            ecx
            eax, DWORD PTR _str$[ebp] ; place pointer to string
   mov
   from "str"
   mov
            DWORD PTR eos$[ebp], eax ; place it to local
   variable "eos"
$LN2@strlen_:
            ecx, DWORD PTR _eos$[ebp] ; ECX=eos
   mov
    ; take 8-bit byte from address in ECX and place it as 32-bit
   value to EDX with sign extension
            edx, BYTE PTR [ecx]
    movsx
    mov
            eax, DWORD PTR _eos$[ebp]
                                       : EAX=eos
    add
            eax, 1
                                        increment EAX
                                       ; place EAX back to "eos"
    mov
            DWORD PTR eos$[ebp], eax
            edx, edx
                                        ; EDX is zero?
    test
            SHORT $LN1@strlen_
                                      ; yes, then finish loop
    je
            SHORT $LN2@strlen
                                       ; continue loop
    jmp
$LN1@strlen :
    ; here we calculate the difference between two pointers
           eax, DWORD PTR _eos$[ebp]
    mov
           eax, DWORD PTR str$[ebp]
    sub
                                        : subtract 1 and return
    sub
           eax, 1
   result
           esp, ebp
    mov
           ebp
   pop
    ret
           0
strlen ENDP
```

We get two new instructions here: MOVSX and TEST.

The first one – MOVSX – takes a byte from an address in memory and stores the value in a 32-bit register. MOVSX stands for *MOV with Sign-Extend*. MOVSX sets the rest of the bits, from the 8th to the 31th, to 1 if the source byte is *negative* or to 0 if is *positive*.

And here is why.

By default, the *char* type is signed in MSVC and GCC. If we have two values of which one is *char* and the other is *int*, (*int* is signed too), and if the first value contain -2 (coded as 0xFE) and we just copy this byte into the *int* container, it makes 0x00000FE, and this from the point of signed *int* view is 254, but not -2. In signed int, -2 is coded as 0xFFFFFFE. So if we need to transfer 0xFE from a variable of *char* type to *int*, we need to identify its sign and extend it. That is what MOVSX does.

You can also read about it in "Signed number representations" section (22 on page 157).

It's hard to say if the compiler needs to store a *char* variable in EDX, it could just take a 8-bit register part (for example DL). Apparently, the compiler's register allocator works like that.

Then we see TEST EDX, EDX. You can read more about the TEST instruction in the section about bit fields (17 on page 112). Here this instruction just checks if the value in EDX equals to 0.

Optimizing MSVC

Now let's compile all this in MSVC 2012, with optimizations turned on (/Ox):

		Listing 14.1: Optimizing MSVC 201	27	/060
_str\$ =		; size = 4		
_strlen	mov	<pre>edx, DWORD PTR _str\$[esp-4]</pre>		FDX -> nointer to
the	string		'	
	mov	eax, edx	;	move to EAX
\$LL2@str	len:			
	mov	cl, BYTE PTR [eax]		CL = *EAX
	inc	eax	'	EAX++
		cl, cl	'	CL==0?
	jne sub	SHORT \$LL2@strlen eax, edx		no, continue loop calculate pointers
diff	erence		'	carculate pointers
GITT	dec	eax	;	decrement EAX
	ret	0		
_strlen	ENDP			

Listing 14.1: Optimizing MSVC 2012 /Ob0

Now it is all simpler. Needless to say, the compiler could use registers with such efficiency only in small functions with a few local variables.

INC/DEC – are increment/decrement instructions, in other words: add or substract 1 to/from a variable.

Chapter 15

Replacing arithmetic instructions to other ones

In the pursuit of optimization, one instruction may be replaced by another, or even with a group of instructions. For example, ADD and SUB can replace each other: line 18 in listing.??

15.1 Multiplication

15.1.1 Multiplication using addition

Here is a simple example:

```
Listing 15.1: Optimizing MSVC 2010
```

```
unsigned int f(unsigned int a)
{
    return a*8;
};
```

Multiplication by 8 is replaced by 3 addition instructions, which do the same. Apparently, MSVC's optimizer decided that this code can be faster.

; size 🖌

```
CHAPTER 15. REPLACING ARITHMETIC INSTRUCTIONS TO OTHERHOMER 15. REPLACING ARITHMETIC INSTRUCTIONS TO OTHER ONES
```

_TEXT EN	ld eax, ld eax, ld eax,	eax	PTR	_a\$[es	p-4]		
END							

15.1.2 Multiplication using shifting

Multiplication and division instructions by a numbers that's a power of 2 are often replaced by shift instructions.

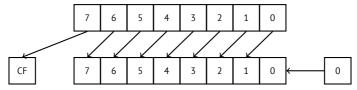

```
unsigned int f(unsigned int a)
{
    return a*4;
};
```

Listing 15.2: Non-optimizing MSVC 2010

f PROC	
push ebp mov ebp,	esp DWORD PTR _a\$[ebp] 2

Multiplication by 4 is just shifting the number to the left by 2 bits and inserting 2 zero bits at the right (as the last two bits). It is just like multiplying 3 by 100 - we need to just add two zeroes at the right.

That's how the shift left instruction works:

The added bits at right are always zeroes.

CHAPTER 15. REPLACING ARITHMETIC INSTRUCTIONS TO OTHER MORES 15. REPLACING ARITHMETIC INSTRUCTIONS TO OTHER ONES

15.1.3 Multiplication using shifting, subtracting, and adding

It's still possible to get rid of the multiplication operation when you multiply by numbers like 7 or 17 again by using shifting. The mathematics used here is relatively easy.

32-bit

```
#include <stdint.h>
int f1(int a)
{
            return a*7;
};
int f2(int a)
{
            return a*28;
};
int f3(int a)
{
            return a*17;
};
```

x86

Listing 15.3: Optimizing MSVC 2012

```
; a*7
_a$ = 8
_f1
        PROC
                 ecx, DWORD PTR a$[esp-4]
        mov
; ECX=a
        lea
                 eax, DWORD PTR [ecx*8]
 EAX=ECX*8
        sub
                 eax, ecx
; EAX=EAX-ECX=ECX*8-ECX=ECX*7=a*7
        ret
                 0
_f1
        ENDP
; a*28
_a$ = 8
 f2
        PROC
```

```
CHAPTER 15. REPLACING ARITHMETIC INSTRUCTIONS TO OTHER IMMEET 15. REPLACING ARITHMETIC INSTRUCTIONS TO OTHER ONES
                  ecx, DWORD PTR _a$[esp-4]
         mov

        mov
        ret
; a*17
f3:
                 rax, rdi
        mov
        sal
                 rax, 4
; RAX=RAX<<4=a*16
        add
                 rax, rdi
 RAX=a*16+a=a*17
        ret
```

15.2 Division

15.2.1 Division using shifts

Example of division by 4:

```
unsigned int f(unsigned int a)
{
     return a/4;
};
```

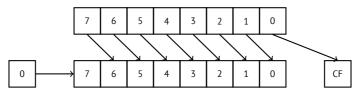

We get (MSVC 2010):

Listing 15.5: MSVC 2010

_a\$	5 = 8		; size 🖌
	l		
_f	PROC		
	mov	eax, DWORD PTR _a\$[esp-4]	
	shr	eax, 2	
	ret	0	
_f	ENDP		

The SHR (*SHift Right*) instruction in this example is shifting a number by 2 bits to the right. The two freed bits at left (e.g., two most significant bits) are set to zero. The two least significant bits are dropped. In fact, these two dropped bits are the division operation remainder.

The SHR instruction works just like SHL, but in the other direction.

It is easy to understand if you imagine the number 23 in the decimal numeral system. 23 can be easily divided by 10 just by dropping last digit (3-division remainder). 2 is left after the operation as a quotient.

So the remainder is dropped, but that's OK, we work on integer values anyway, these are not a real numbers!

Chapter 16

Arrays

An array is just a set of variables in memory that lie next to each other and that have the same type¹.

16.1 Simple example

```
#include <stdio.h>
int main()
{
    int a[20];
    int i;
    for (i=0; i<20; i++)
        a[i]=i*2;
    for (i=0; i<20; i++)
        printf ("a[%d]=%d\n", i, a[i]);
    return 0;
};</pre>
```

¹AKA² "homogeneous container"

16.1.1 x86

MSVC

Let's compile:

Listing 16.1: MSVC 2008

```
TEXT SEGMENT
i$ = -84
                                : size = 4

          eax
   push OFFSET $SG2463
   call
          _printf
         esp, 12
                         ; 000000cH
   add
         SHORT $LN2@main
   jmp
```

\$LN1@main:		
xor	eax,	eax
mov	esp,	ebp
рор	ebp	
ret	0	
_main	ENDP	

Nothing very special, just two loops: the first is a filling loop and second is a printing loop. The shl ecx, 1 instruction is used for value multiplication by 2 in ECX, more about below 15.2.1 on page 92.

80 bytes are allocated on the stack for the array, 20 elements of 4 bytes.

16.2 Buffer overflow

16.2.1 Reading outside array bounds

So, array indexing is just *array[index]*. If you study the generated code closely, you'll probably note the missing index bounds checking, which could check *if it is less than 20*. What if the index is 20 or greater? That's the one C/C++ feature it is often blamed for.

Here is a code that successfully compiles and works:

```
#include <stdio.h>
int main()
{
    int a[20];
    int i;
    for (i=0; i<20; i++)
        a[i]=i*2;
    printf ("a[20]=%d\n", a[20]);
    return 0;
};</pre>
```

Compilation results (MSVC 2008):

Listing 16.2: Non-optimizing MSVC 2008

\$SG2474 DB 'a[20]=%d', OaH, OOH _i\$ = -84 ; size = 4 CHAPTER 16. ARRAYS

Figure 16.3: OllyDbg: EIP was restored, but OllyDbg can't disassemble at 0x15

Now please keep your eyes on the registers.

EIP is 0x15 now. It is not a legal address for code-at least for win32 code! We got there somehow against our will. It is also interesting that the EBP register contain 0x14, ECX and EDX-0x1D.

Let's study stack layout a bit more.

After the control flow was passed to main(), the value in the EBP register was saved on the stack. Then, 84 bytes were allocated for the array and the *i* variable. That's (20+1)*sizeof(int). ESP now points to the _i variable in the local stack and after the execution of the next PUSH something, *something* is appearing next to _i.

That's the stack layout while the control is in main():

ESP	4 bytes allocated for <i>i</i> variable
ESP+4	80 bytes allocated for a [20] array
ESP+84	saved EBP value
ESP+88	return address

a[19]=something statement writes the last *int* in the bounds of the array (in bounds so far!)

a[20]=something statement writes *something* to the place where the value of EBP is saved.

Please take a look at the register state at the moment of the crash. In our case, 20 was written in the 20th element. At the function end, the function epilogue restores the original EBP value. (20 in decimal is 0x14 in hexadecimal). Then RET gets executed, which is effectively equivalent to POP EIP instruction.

The RET instruction takes the return address from the stack (that is the address in CRT), which was called main()), and 21 iss stored there (0x15 in hexadecimal). The CPU traps at address 0x15, but there is no executable code there, so exception gets raised.

Welcome! It is called a *buffer overflow*³.

Replace the *int* array with a string (*char* array), create a long string deliberately and pass it to the program, to the function, which doesn't check the length of the string and copies it in a short buffer, and you'll able to point the program to an address to which it must jump. It's not that simple in reality, but that is how it emerged⁴

16.3 One more word about arrays

Now we understand why it is impossible to write something like this in C/C++ code:

```
void f(int size)
{
    int a[size];
...
};
```

That's just because the compiler must know the exact array size to allocate space for it in the local stack layout on at the compiling stage.

If you need an array of arbitrary size, allocate it by using malloc(), then access the allocated memory block as an array of variables of the type you need.

Or use the C99 standard feature [ISO07, pp. 6.7.5/2], and it works like alloca() (5.2.4 on page 17) internally.

It's also possible to use garbage collecting libraries for C. And there are also libraries supporting smart pointers for C++.

³wikipedia

⁴Classic article about it: [One96].

16.4 Array of pointers to strings

Here is an example for an array of pointers.

Listing	16.4:	Get	month	name

```
#include <stdio.h>
const char* month1[]=
{
        "January",
        "February",
        "March",
        "April",
        "May",
        "June",
        "July",
        "August",
        "September",
        "October",
        "November"
        "December"
};
// in 0..11 range
const char* get_month1 (int month)
{
        return month1[month];
};
```

16.4.1 x64

_DATA	ENDS						
month\$ =	= 8						
get_mon	th1 PROC						
	movsxd	rax, ecx					
	lea	<pre>rcx, OFFSET FLAT:month1</pre>					
	mov	<pre>rax, QWORD PTR [rcx+rax*8]</pre>					
	ret	0					
get_mon	th1 ENDP						

The code is very simple:

- The first MOVSXD instruction copies a 32-bit value from ECX (where *month* argument is passed) to RAX with sign-extension (because the *month* argument is of type *int*). The reason for the sign extension is that this 32-bit value is to be used in calculations with other 64-bit values. Hence, it has to be promoted to 64-bit⁵.
- Then the address of the pointer table is loaded into RCX.
- Finally, the input value (*month*) is multiplied by 8 and added to the address. Indeed: we are in a 64-bit environment and all address (or pointers) require exactly 64 bits (or 8 bytes) for storage. Hence, each table element is 8 bytes wide. And that's why to pick a specific element, *month* * 8 bytes has to be skipped from the start. That's what MOV does. In addition, this instruction also loads the element at this address. For 1, an element would be a pointer to a string that contains "February", etc.

Optimizing GCC 4.9 can do the job even better⁶:

⁵It is somewhat weird, but negative array index could be passed here as *month*. And if this happens, the negative input value of *int* type is sign-extended correctly and the corresponding element before table is picked. It is not going to work correctly without sign-extension.

⁶"0+" was left in the listing because GCC assembler output is not tidy enough to eliminate it. It's *displacement*, and it's zero here.

Listing 16.6: Optimizing GCC 4.9 x64 rdi, edi

movsx rdi, edi mov rax, QWORD PTR month1[0+rdi*8] ret

32-bit MSVC

Let's also compile it in the 32-bit MSVC compiler:

```
Listing 16.7: Optimizing MSVC 2013 x86
```

```
_month$ = 8
_get_month1 PROC
            mov eax, DWORD PTR _month$[esp-4]
            mov eax, DWORD PTR _month1[eax*4]
            ret 0
_get_month1 ENDP
```

The input value does not need to be extended to 64-bit value, so it is used as is. And it's multiplied by 4, because the table elements are 32-bit (or 4 bytes) wide.

16.5 Multidimensional arrays

Internally, a multidimensional array is essentially the same thing as a linear array. Since the computer memory is linear, it is an one-dimensional array. For convenience, this multi-dimensional array can be easily represented as one-dimensional.

For example, this is how the elements of the 3x4 array are placed in one-dimensional array of 12 cells:

Offset in memory	array element
0	[0][0]
1	[0][1]
2	[0][2]
3	[0][3]
4	[1][0]
5	[1][1]
6	[1][2]
7	[1][3]
8	[2][0]
9	[2][1]
10	[2][2]
11	[2][3]

Table 16.1: Two-dimensional array represented in memory as one-dimensional

Here is how each cell of 3*4 array are placed in memory:

0	1	2	3
4	5	6	7
8	9	10	11

Table 16.2: Memory addresses of each cell of two-dimensional array

So, in order to calculate the address of the element we need, we first multiply the first index by 4 (array width) and then add the second index. That's called *row-major order*, and this method of array and matrix representation is used in at least C/C++ and Python. The term *row-major order* in plain English language means: "first, write the elements of the first row, then the second row ...and finally the elements of the last row".

Another method for representation is called *column-major order* (the array indices are used in reverse order) and it is used at least in FORTRAN, MATLAB and R. *column-major order* term in plain English language means: "first, write the elements of the first column, then the second column ...and finally the elements of the last column".

Which method is better? In general, in terms of performance and cache memory, the best scheme for data organization is the one, in which the elements are accessed sequentially. So if your function accesses data per row, *row-major order* is better, and vice versa.

16.5.1 Two-dimensional array example

We are going to work with an array of type *char*, which implies that each element requires only one byte in memory.

Row filling example

Let's fill the second row with these values 0..3:

Listing 1	16.8:	Row	filling	example
-----------	-------	-----	---------	---------

All three rows are marked with red. We see that second row now has values 0, 1, 2 and 3:

Address													
00C33370													
00033380													
00033390													
00C333A0													
00C333B0	00	00	00	00	00	00	00	00	00	00	00	00	00

Column filling example

Let's fill the third column with values: 0..2:

```
Listing 16.9: Column filling example
```

The three rows are also marked in red here. We see that in each row, at third position these values are written: 0, 1 and 2.

Address													
01033380	00	00	00	00	00	00	01	00	00	00	02	00	02
01033390													
010333A0													
010333B0	00	00	00	00	00	00	00	00	00	00	00	00	00

Figure 16.5: OllyDbg: array is filled

16.5.2 Access two-dimensional array as one-dimensional

We can be easily assured that it's possible to access a two-dimensional array as one-dimensional array in at least two ways:

```
#include <stdio.h>
char a[3][4];
```

```
char get_by_coordinates1 (char array[3][4], int a, int b)
{
        return array[a][b];
};
char get_by_coordinates2 (char *array, int a, int b)
{
        // treat input array as one-dimensional
        // 4 is array width here
        return array[a*4+b];
};
char get_by_coordinates3 (char *array, int a, int b)
{
        // treat input array as pointer,
        // calculate address, get value at it
        // 4 is array width here
        return *(array+a*4+b);
};
int main()
{
        a[2][3]=123;
        printf ("%d\n", get_by_coordinates1(a, 2, 3));
        printf ("%d\n", get_by_coordinates2(a, 2, 3));
        printf ("%d\n", get_by_coordinates3(a, 2, 3));
};
```

Compile and run it: it shows correct values.

What MSVC 2013 did is fascinating, all three routines are just the same!

Listing 16.10: Optimizing MSVC 2013 x64

```
array = 8
a^{=} 16
bs = 24
get_by_coordinates3 PROC
; RCX=address of array
; RDX=a
; R8=b
        movsxd rax, r8d
 EAX=b
        movsxd
                r9, edx
 R9=a
        add
                rax, rcx
 RAX=b+address of array
        movzx
                eax, BYTE PTR [rax+r9*4]
```

```
; AL=load byte at address RAX+R9*4=b+address of
   array+a*4=address of array+a*4+b
        ret
                0
get_by_coordinates3 ENDP
array = 8
a = 16
bs = 24
get_by_coordinates2 PROC
        movsxd
                rax, r8d
                r9, edx
        movsxd
        add
                rax, rcx
                eax, BYTE PTR [rax+r9*4]
        movzx
        ret
                0
get_by_coordinates2 ENDP
arrav = 8
a^{=}16
b = 24
get_by_coordinates1 PROC
        movsxd rax, r8d
        movsxd
                r9, edx
        add
                rax, rcx
                eax, BYTE PTR [rax+r9*4]
        movzx
        ret
                0
get by coordinates1 ENDP
```

16.5.3 Three-dimensional array example

It's thing in multidimensional arrays. Now we are going to work with an array of type *int*: each element requires 4 bytes in memory.

Let's see:

Listing 16.11: simple example

x86

We get (MSVC 2010):

Listing 16.12: MSVC 2010

	3	
_DATA		
COMM	_a:DWORD:01770H	
_DATA	ENDS	
PUBLIC	_insert	
_TEXT	SEGMENT	
_x\$ = 8	; size = 4	
_y\$ = 12	; size = 4	
_z\$ = 16	; size = 4	
_value\$ =	: 20 ; size = 4	
_insert	PROC	
push	ebp	
mov	ebp, esp	
	eax, DWORD PTR _x\$[ebp]	
imul	eax, 2400	; eax=600*4*x
	ecx, DWORD PTR _y\$[ebp]	
	ecx, 120	; ecx=30*4*y
	edx, DWORD PTR _a[eax+ecx]	; edx=a + 600*4*x + ∠
	4*y	
	eax, DWORD PTR _z\$[ebp]	
mov	<pre>ecx, DWORD PTR _value\$[ebp]</pre>	
mov		; *(edx+z*4)=value
	ebp	
ret	0	
	ENDP	
_TEXT	ENDS	

Nothing special. For index calculation, three input arguments are used in the formula $address = 600 \cdot 4 \cdot x + 30 \cdot 4 \cdot y + 4z$, to represent the array as multidimensional. Do not forget that the *int* type is 32-bit (4 bytes), so all coefficients must be multiplied by 4.

Listing 16.13: GCC 4.4.1

insert	public insert proc near
x y z value	<pre>= dword ptr 8 = dword ptr 0Ch = dword ptr 10h = dword ptr 14h</pre>
	push ebp

	mov	ebp,	esp		
	push	ebx			
	mov	ebx,	[ebp+x]		
	mov	eax,	[ebp+y]		
	mov	ecx,	[ebp+z]		
	lea	edx,	[eax+eax]		edx=y*2
	mov	eax,	edx		eax=y*2
	shl	eax,	4	;	eax=(y*2)∠
, <<4 = y*2					
		eax,	edx	;	eax=y*32 ∠
⊊ - y*2=y*3					
	imul		ebx, 600		edx=x*600
	add	eax,	edx	;	eax=eax+∠
⊊ edx=y*30	_				
	lea	edx,	[eax+ecx]	;	edx=y*30 ∠
⊊ + x*600 +					
	mov		[ebp+value]		
	mov	dwor	d ptr ds:a[edx*4], eax	;	*(a+edx∠
⊊ *4)=value					
	рор	ebx			
	рор	ebp			
	retn				
insert	endp				

The GCC compiler does it differently. For one of the operations in the calculation (30y), GCC produces code without multiplication instructions. This is how it done: $(y+y) \ll 4 - (y+y) = (2y) \ll 4 - 2y = 2 \cdot 16 \cdot y - 2y = 32y - 2y = 30y$. Thus, for the 30y calculation, only one addition operation, one bitwise shift operation and one subtraction operation are used. This works faster.

16.6 Conclusion

An array is a pack of values in memory located adjacently. It's true for any element type, including structures. Access to a specific array element is just a calculation of its address.

Chapter 17

Manipulating specific bit(s)

A lot of functions define their input arguments as flags in bit fields. Of course, they could be substituted by a set of *bool*-typed variables, but it is not frugally.

17.1 Specific bit checking

17.1.1 x86

Win32 API example:

```
HANDLE fh;
```

```
fh=CreateFile ("file", GENERIC_WRITE | GENERIC_READ, ∠
    FILE_SHARE_READ, NULL, OPEN_ALWAYS, FILE_ATTRIBUTE_NORMAL∠
    , NULL);
```

We get (MSVC 2010):

Listing 17.1: MSVC 2010

push	0		
push	128	;	2
↓ 00000080H			
push	4		
push	0		
push	1		
push	-1073741824	;	2
push	OFFSET \$SG78813		

CHAPTER 17. MANIPULATING SPECIFIC BIT(S)

call	DWORD	PTR	impCrea	ateFileA@28
mov	DWORD	PTR	_fh\$[ebp],	eax

Let's take a look in WinNT.h:

Listing 17.2: WinNT.h

#define	GENERIC_READ	(0x8000000L)
#define	GENERIC_WRITE	(0x4000000L)
#define	GENERIC_EXECUTE	(0x2000000L)
#define	GENERIC_ALL	(0x1000000L)

Everything is clear, GENERIC_READ | GENERIC_WRITE = 0×80000000 | 0×40000000 = $0 \times C0000000$, and that value is used as the second argument for the CreateFile()¹function.

How would CreateFile() check these flags? If we look in KERNEL32.DLL in Windows XP SP3 x86, we'll find this fragment of code in CreateFileW:

		,
.text:7C83D429	test	byte ptr [ebp+∠
└y dwDesiredAccess+3], 40h		
.text:7C83D42D	mov	[ebp+var_8], 1
.text:7C83D434	jz	short loc_7C83D417
.text:7C83D436	jmp	loc_7C810817

Here we see the TEST instruction, however it doesn't take the whole second argument, but only the most significant byte (ebp+dwDesiredAccess+3) and checks it for flag 0x40 (which implies the GENERIC_WRITE flag here) TEST is basically the same instruction as AND, but without saving the result (recall the fact CMP is merely the same as SUB, but without saving the result (7.3.1 on page 35)).

The logic of this code fragment is as follows:

if ((dwDesiredAccess&0x4000000) == 0) goto loc_7C83D417

If AND instruction leaves this bit, the ZF flag is to be cleared and the JZ conditional jump is not to be triggered. The conditional jump is triggered only if the 0x40000000 bit is absent in dwDesiredAccess variable —then the result of AND is 0, ZF is to be set and the conditional jump is to be triggered.

17.2 Setting and clearing specific bits

For example:

¹msdn.microsoft.com/en-us/library/aa363858(VS.85).aspx

```
#include <stdio.h>
#define IS_SET(flag, bit) ((flag) & (bit))
#define SET_BIT(var, bit) ((var) |= (bit))
#define REMOVE_BIT(var, bit) ((var) &= ~(bit))
int f(int a)
{
    int rt=a;
    SET_BIT (rt, 0x4000);
    REMOVE_BIT (rt, 0x200);
    return rt;
};
int main()
{
    f(0x12340678);
};
```

17.2.1 x86

Non-optimizing MSVC

We get (MSVC 2010):

Listing 17.4: MSVC 2010

```
_{rt} = -4
                   ; size = 4
_a$ = 8
                   ; size = 4
f PROC
    push
           ebp
           ebp, esp
    mov
    push
           ecx
           eax, DWORD PTR _a$[ebp]
    mov
           DWORD PTR rt$[ebp], eax
    mov
           ecx, DWORD PTR _rt$[ebp]
    mov
                                       : 00004000H
    or
           ecx, 16384
           DWORD PTR _rt$[ebp], ecx
    mov
    mov
           edx, DWORD PTR _rt$[ebp]
                                      ; fffffdffH
    and
           edx, -513
           DWORD PTR _rt$[ebp], edx
    mov
           eax, DWORD PTR rt$[ebp]
    mov
           esp, ebp
    mov
```

CHAPTER 17. MANIPULATING SPECIFIC BIT(S)

pop ebp ret 0 _f ENDP

The OR instruction sets one bit to value while ignoring the rest.

AND resets one bit. It can be said that AND just copies all bits except one. Indeed, in the second AND operand only the bits that need to be saved are set, just the one do not want to copy is not (which is 0 in the bitmask). It is the easier way to memorize the logic.

Optimizing MSVC

If we compile it in MSVC with optimization turned on (/0x), the code is even shorter:

_a\$ _f	= 8 PROC			; size = 4
_	mo∨ and		DWORD -513	PTR _a\$[esp-4] ; fffffdffH
	or		16384	; 00004000Н
_f	ret ENDP	0		

17.3 Shifts

Bit shifts in C/C++ are implemented using \ll and \gg operators.

The x86 ISA has the SHL (SHift Left) and SHR (SHift Right) instructions for this.

Shift instructions are often used in division and multiplications by powers of two: 2^n (e.g., 1, 2, 4, 8, etc): 15.1.2 on page 88, 15.2.1 on page 91.

Shifting operations are also so important because they are often used for specific bit isolation or for constructing a value of several scattered bits.

17.4 Counting bits set to 1

Here is a simple example of a function that calculates the number of bits set in the input value.

This operation is also called "population count"².

```
#include <stdio.h>
#define IS_SET(flag, bit) ((flag) & (bit))
int f(unsigned int a)
{
    int i;
    int rt=0;
    for (i=0; i<32; i++)
        if (IS_SET (a, 1<<i))
            rt++;
    return rt;
};
int main()
{
    f(0x12345678); // test
};
</pre>
```

In this loop, the iteration count value *i* is counting from 0 to 31, so the $1 \ll i$ statement is counting from 1 to 0x80000000. Describing this operation in natural language, we would say *shift 1 by n bits left*. In other words, $1 \ll i$ statement consequently produces all possible bit positions in a 32-bit number. The freed bit at right is always cleared.

Here is a table of all possible $1 \ll i$ for $i = 0 \dots 31$:

²modern x86 CPUs (supporting SSE4) even have a POPCNT instruction for it

CHAPTER 17. MANIPULATING SPECIFIC BIT(S)

C/C++ expression	Power of two	Decimal form	Hexadecimal form
1 << 0	1	1	1
1 ~ 1	2^{1}	2	2
$1 \ll 2$	2^{2}	4	4

	•		•

These constant numbers (bit masks) very often appear in code and a practicing reverse engineer must be able to spot them quickly. You probably haven't to memorize the decimal numbers, but the hexadecimal ones are very easy to remember.

These constants are very often used for mapping flags to specific bits. For example, here is excerpt from ssl_private.h from Apache 2.4.6 source code:

/**

* Define the SSL options

+/

· /		
#define	SSL_OPT_NONE	(0)
	SSL_OPT_RELSET	(1<<0)
#define	SSL_OPT_STDENVVARS	(1<<1)
#define	SSL_OPT_EXPORTCERTDATA	(1<<3)
#define	SSL_OPT_FAKEBASICAUTH	(1<<4)
	SSL_OPT_STRICTREQUIRE	
	SSL_OPT_OPTRENEGOTIATE	
#define	SSL_OPT_LEGACYDNFORMAT	(1<<7)

Let's get back to our example.

The IS_SET macro checks bit presence in *a*. The IS_SET macro is in fact the logical AND operation (*AND*) and it returns 0 if the specific bit is absent there, or the bit mask, if the bit is present. *The if(*) operator in C/C++ triggers if the expression in it is not zero, it might be even 123456, that is why it always works correctly.

17.4.1 x86

MSVC

Let's compile (MSVC 2010):

```
Listing 17.6: MSVC 2010
```

```
rts = -8
                      ; size = 4
i$ = -4
                      ; size = 4
a$ = 8
                      : size = 4
f PROC
   push
           ebp
    mov
           ebp, esp
    sub
           esp, 8
           DWORD PTR rt$[ebp], 0
    mov
           DWORD PTR _i$[ebp], 0
   mov
           SHORT $LN4@f
   jmp
$LN3@f:
           eax, DWORD PTR _i$[ebp] ; increment of i
   mov
    add
           eax, 1
    mov
           DWORD PTR _i$[ebp], eax
$LN4@f:
                                       ; 00000020H
   cmp
           DWORD PTR i$[ebp], 32
           SHORT $LN2@f
                                       ; loop finished?
   jge
           edx, 1
    mov
   mov
           ecx, DWORD PTR _i$[ebp]
    shl
           edx, cl
                                       : EDX=EDX<<CL
    and
           edx, DWORD PTR a$[ebp]
```

CHAPTER 17. MANIPULATING SPECIFIC BIT(S)			CHAPTER 17. MANIPULATING SPECIFIC BIT(S)

17.4.2 x64

Let's modify the example slightly to extend it to 64-bit:

```
#include <stdio.h>
#include <stdint.h>
#define IS_SET(flag, bit) ((flag) & (bit))
int f(uint64_t a)
{
    uint64_t i;
    int rt=0;
    for (i=0; i<64; i++)
        if (IS_SET (a, 1ULL<<i))</pre>
            rt++;
    return rt;
};
```

Optimizing MSVC 2010

Listing 17.7: MSVC 2010

```
a$ = 8
f
        PROC
; RCX = input value
        xor
                eax, eax
```

```
edx, 1
        mov
        lea
                r8d, QWORD PTR [rax+64]
; R8D=64
                5
        npad
$LL4@f:
        test
                rdx, rcx
; there are no such bit in input value?
; skip the next INC instruction then.
                SHORT $LN3@f
        je
        inc
                        : rt++
                eax
$LN3@f:
        rol
                rdx, 1 ; RDX=RDX<<1
        dec
                r8
                        ; R8--
                SHORT $LL4@f
        ine
        fatret
                0
f
        ENDP
```

Here the ROL instruction is used instead of SHL, which is in fact "rotate left" instead of "shift left", but in this example it works just as SHL.

R8 here is counting from 64 to 0. It's just like an inverted *i*.

Here is a table of some registers during the execution:

RDX	R8
0x000000000000000000000000000000000000	64
0x0000000000000000	63
0x000000000000000004	62
0x000000000000008	61
0x400000000000000000	2
0x800000000000000000000000000000000000	1

Optimizing MSVC 2012

Listing 17.8: MSVC 2012

```
a$ = 8
f     PROC
; RCX = input value
     xor     eax, eax
     mov     edx, 1
     lea     r8d, QWORD PTR [rax+32]
; EDX = 1, R8D = 32
     npad    5
$LL4@f:
; pass 1 ------
```

```
rdx, rcx
       test
              SHORT $LN3@f
       je
       inc
                      ; rt++
              eax
$LN3@f:
              rdx, 1 ; RDX=RDX<<1
       rol
 pass 2 -----
              rdx, rcx
       test
             SHORT $LN11@f
       je
       inc
             eax : rt++
$LN11@f:
       rol
              rdx, 1 ; RDX=RDX<<1
              r8 ; R8--
       dec
              SHORT $LL4@f
       jne
       fatret 0
f
       FNDP
```

Optimizing MSVC 2012 does almost the same job as optimizing MSVC 2010, but somehow, it generates two identical loop bodies and the loop count is now 32 instead of 64. To be honest, it's not possible to say why. Some optimization trick? Maybe it's better for the loop body to be slightly longer? Anyway, such code is relevant here to show that sometimes the compiler output may be really weird and illogical, but perfectly working.

17.5 Conclusion

CHAPTER 17. MANIPULATING SPECIFIC BIT(S)

Analogous to the C/C++ shifting operators \ll and \gg , the shift instructions in x86 are SHR/SHL (for unsigned values) and SAR/SHL (for signed values).

The shift instructions in ARM are LSR/LSL (for unsigned values) and ASR/LSL (for signed values). It's also possible to add shift suffix to some instructions (which are called "data processing instructions").

17.5.1 Check for specific bit (known at compile stage)

Test if the 1000000 bit (0x40) is present in the register's value:

```
Listing 17.9: C/C++
```

```
if (input&0x40)
```

```
• • •
```

Listing 17.1	0:	x86
--------------	----	-----

TEST REG, 40h JNZ is_set ; bit is not set

Listing 17.11: x86

TEST REG, 40h
JZ is_cleared
; bit is set

Sometimes, AND is used instead of TEST, but the flags that are set are the same.

17.5.2 Check for specific bit (specified at runtime)

This is usually done by this C/C++ code snippet (shift value by n bits right, then cut off lowest bit):

Listing 17.12: C/C++

if ((value>>n)&1)

This is usually implemented in x86 code as:

Listing 17.13: x86

; REG=input_value ; CL=n SHR REG, CL AND REG, 1

Or (shift 1 bit *n* times left, isolate this bit in input value and check if it's not zero):

Listing 17.14: C/C++

if (value & (1<<n))

This is usually implemented in x86 code as:

Listing 17.15: x86

; CL=n MOV REG, 1 SHL REG, CL AND input_value, REG

17.5.3 Set specific bit (known at compile stage)

Listing 17.16: C/C++

value=value|0x40;

Listing 17.17: x86

OR REG, 40h

17.5.4 Set specific bit (specified at runtime)

Listing 17.18: C/C++

value=value|(1<<n);

This is usually implemented in x86 code as:

Listing 17.19: x86

; CL=n MOV REG, 1 SHL REG, CL OR input_value, REG

17.5.5 Clear specific bit (known at compile stage)

Just apply AND operation with the inverted value:

Listing 17.20: C/C++

value=value&(~0x40);

Listing 17.21: x86

AND REG, OFFFFFBFh

```
Listing 17.22: x64
```

```
AND REG, OFFFFFFFFFFFFFFFF
```

This is actually leaving all bits set except one.

17.5.6 Clear specific bit (specified at runtime)

Listing 17.23: C/C++

value=value&(~(1<<n));</pre>

Listing 17.24: x86

; CL=n MOV REG, 1 SHL REG, CL NOT REG AND input_value, REG

Chapter 18

Linear congruential generator as pseudorandom number generator

The linear congruential generator is probably the simplest possible way to generate random numbers. It's not in favour in modern times¹, but it's so simple (just one multiplication, one addition and one AND operation), we can use it as an example.

```
#include <stdint.h>
// constants from the Numerical Recipes book
#define RNG_a 1664525
#define RNG_c 1013904223
static uint32_t rand_state;
void my_srand (uint32_t init)
{
    rand_state=init;
}
int my_rand ()
{
    rand_state=rand_state*RNG_a;
    rand_state=rand_state*RNG_c;
    return rand_state & 0x7fff;
}
```

¹Mersenne twister is better

There are two functions: the first one is used to initialize the internal state, and the second one is called to generate pseudorandom numbers.

We see that two constants are used in the algorithm. They are taken from [Pre+07]. Let's define them using a #define C/C++ statement. It's a macro. The difference between a C/C++ macro and a constant is that all macros are replaced with their value by C/C++ preprocessor, and they don't take any memory, unlike variables. In contrast, a constant is a read-only variable. It's possible to take a pointer (or address) of a constant variable, but impossible to do so with a macro.

The last AND operation is needed because by C-standard $my_rand()$ has to return a value in the 0..32767 range. If you want to get 32-bit pseudorandom values, just omit the last AND operation.

18.1 x86

		01H DUP (?)
_init\$ = _srand	PROC mov mov ret	eax, DWORD PTR _init\$[esp-4] DWORD PTR _rand_state, eax O
rand	SEGMENT PROC imul add mov and ret ENDP	<pre>eax, 1013904223 ; 3c6ef35fH DWORD PTR _rand_state, eax</pre>
_TEXT	ENDS	

Listing 18.1: Optimizing MSVC 2013

Here we see it: both constants are embedded into the code. There is no memory allocated for them. The my_srand() function just copies its input value into the internal rand_state variable.

my_rand() takes it, calculates the next rand_state, cuts it and leaves it in the EAX register.

The non-optimized version is more verbose:

Listing 18.2: Non-optimizing MSVC 2013	Listing	18.2: Non-o	ptimizing	MSVC 2013
--	---------	-------------	-----------	-----------

_BSS _rand_s _BSS	SEGMENT tate DD ENDS	01H DUP (?)
_init\$ = _srand	PROC push mov mov mov pop ret	ebp ebp, esp eax, DWORD PTR _init\$[ebp] DWORD PTR _rand_state, eax ebp 0
_TEXT _rand	SEGMENT PROC push mov imul mov add mov add mov and pop ret ENDP	<pre>ebp ebp, esp eax, DWORD PTR _rand_state, 1664525 DWORD PTR _rand_state, eax ecx, DWORD PTR _rand_state ecx, 1013904223 ; 3c6ef35fH DWORD PTR _rand_state, ecx eax, DWORD PTR _rand_state eax, 32767 ; 00007fffH ebp 0</pre>
_TEXT	ENDS	

18.2 x64

The x64 version is mostly the same and uses 32-bit registers instead of 64-bit ones (because we are working with *int* values here). But my_srand() takes its input argument from the ECX register rather than from stack:

Listing 18.3: Optimizing MSVC 2013 x64

```
_BSS SEGMENT

   ↓ 0019660dH
       add
               eax, 1013904223
                                                       ; 32
   └ c6ef35fH
       mov
             DWORD PTR rand_state, eax
       and
              eax, 32767
                                                       ; 000072
   └ fffH
              0
       ret
my_rand ENDP
TEXT
       ENDS
```

Chapter 19

Structures

A C/C++ structure, with some assumptions, is just a set of variables, always stored in memory together, not necessary of the same type 1 .

19.1 MSVC: SYSTEMTIME example

Let's take the SYSTEMTIME² win32 structure that describes time.

This is how it's defined:

Listing 19.1: WinBase.h

```
typedef struct _SYSTEMTIME {
  WORD wYear;
  WORD wMonth;
  WORD wDayOfWeek;
  WORD wDay;
  WORD wHour;
  WORD wHour;
  WORD wMinute;
  WORD wSecond;
  WORD wMilliseconds;
} SYSTEMTIME, *PSYSTEMTIME;
```

Let's write a C function to get the current time:

```
#include <windows.h>
#include <stdio.h>
```

```
<sup>1</sup>AKA "heterogeneous container"
<sup>2</sup>MSDN: SYSTEMTIME structure
```

```
void main()
{
   SYSTEMTIME t;
   GetSystemTime (&t);
   printf ("%04d-%02d-%02d %02d:%02d:%02d\n",
       t.wYear, t.wMonth, t.wDay,
       t.wHour, t.wMinute, t.wSecond);
   return;
};
```

We get (MSVC 2010):

```
Listing 19.2: MSVC 2010 /GS-
```

_t\$ = -16 ; size = 16
_main PROC
push ebp
mov ebp, esp
sub esp, 16
lea eax, DWORD PTR _t\$[ebp]
push eax
call DWORD PTRimpGetSystemTime@4
<pre>movzx ecx, WORD PTR _t\$[ebp+12] ; wSecond</pre>
push ecx
<pre>movzx edx, WORD PTR _t\$[ebp+10] ; wMinute</pre>
push edx
<pre>movzx eax, WORD PTR _t\$[ebp+8] ; wHour</pre>
push eax
<pre>movzx ecx, WORD PTR _t\$[ebp+6] ; wDay</pre>
push ecx
<pre>movzx edx, WORD PTR _t\$[ebp+2] ; wMonth</pre>
push edx
<pre>movzx eax, WORD PTR _t\$[ebp] ; wYear</pre>
push eax
push OFFSET \$SG78811 ; '%04d-%02d-%02d %02d:%02d:%02d', 0≠
⊊ аН, ООН
call _printf
add esp, 28
xor eax, eax
mov esp, ebp
pop ebp
ret 0
_main ENDP

16 bytes are allocated for this structure in the local stack — that is exactly sizeof(WORD)*8 (there are 8 WORD variables in the structure).

Pay attention to the fact that the structure begins with the wYear field. It can be said that a pointer to the SYSTEMTIME structure is passed to the GetSystem-Time()³, but it is also can be said that a pointer to the wYear field is passed, and that is the same! GetSystemTime() writes the current year to the WORD pointer pointing to, then shifts 2 bytes ahead, writes current month, etc, etc.

19.1.1 Replacing the structure with array

The fact that the structure fields are just variables located side-by-side, can be easily demonstrated by doing the following. Keeping in mind the SYSTEMTIME structure description, it's possible to rewrite this simple example like this:

The compiler grumbles a bit:

But nevertheless, it produces this code:

Listing 19.3: Non-optimizing MSVC 2010

\$SG78573 DB '%04d-%02d-%02d %02d:%02d:%02d', 0aH, 00H
_array\$ = -16 ; size = 16
_main PROC

³MSDN: SYSTEMTIME structure

	push	ebp
	mov	ebp, esp
	sub	esp, 16
	lea	eax, DWORD PTR _array\$[ebp]
	push	eax
	call	DWORD PTRimpGetSystemTime@4
		<pre>ecx, WORD PTR _array\$[ebp+12] ; wSecond</pre>
	push	ecx
	movzx	edx, WORD PTR _array\$[ebp+10] ; wMinute
	push	edx
	movzx	eax, WORD PTR _array\$[ebp+8] ; wHoure
	push	eax
	movzx	ecx, WORD PTR _array\$[ebp+6] ; wDay
	push	ecx
	movzx	edx, WORD PTR _array\$[ebp+2] ; wMonth
	push	edx
	movzx	eax, WORD PTR _array\$[ebp] ; wYear
	push	eax
	push	OFFSET \$SG78573
	call	_printf
	add	esp, 28
	xor	eax, eax
	mov	esp, ebp
	рор	ebp
	ret	0
_main	ENDP	

And it works just as the same!

It is very interesting that the result in assembly form cannot be distinguished from the result of the previous compilation. So by looking at this code, one cannot say for sure if there was a structure declared, or an array.

Nevertheless, no sane person would do it, as it is not convenient. Also the structure fields may be changed by developers, swapped, etc.

19.2 Let's allocate space for a structure using malloc()

Sometimes it is simpler to place structures not the in local stack, but in the heap:

```
#include <windows.h>
#include <stdio.h>
void main()
{
    SYSTEMTIME *t;
```

```
t=(SYSTEMTIME *)malloc (sizeof (SYSTEMTIME));
GetSystemTime (t);
printf ("%04d-%02d-%02d %02d:%02d:%02d\n",
    t->wYear, t->wMonth, t->wDay,
    t->wHour, t->wMinute, t->wSecond);
free (t);
return;
};
```

Let's compile it now with optimization (/0x) so it would be easy see what we need.

	5 1 5
_main	PROC
push	
push	
call	_malloc
add	esp, 4
mov	,
push	
call	
movzx	
movzx	ecx, WORD PTR [esi+10] ; wMinute
movzx	. ,
push	
movzx	, , ,
push	
movzx	, ,
push	
movzx	, ,
push	
push	
push	
push	
	_printf
push	
call	-
add	esp, 32
xor	eax, eax
рор	esi
ret	0
_main	ENDP

So, sizeof(SYSTEMTIME) = 16 and that is exact number of bytes to be allocated by malloc(). It returns a pointer to a freshly allocated memory block in the EAX register, which is then moved into the ESI register. GetSystemTime() win32 function takes care of saving value in ESI, and that is why it is not saved here and continues to be used after the GetSystemTime() call.

New instruction -MOVZX (*Move with Zero eXtend*). It may be used in most cases as MOVSX, but it sets the remaining bits to 0. That's because printf() requires a 32-bit *int*, but we got a WORD in the structure -that is 16-bit unsigned type. That's why by copying the value from a WORD into *int*, bits from 16 to 31 must be cleared, because a random noise may be there, which is left from the previous operations on the register(s).

In this example, it's possible to represent the structure as an array of 8 WORDs:

We get:

Listing 19.5: Optimizing MSVC

\$SG78594 DB	'%04d-%02d-%02d %02d:%02d:%02d', 0aH, 00H
_main PROC push push call add mov	esi 16 _malloc esp, 4 esi, eax

movzx push movzx push movzx push movzx push push call push call	<pre>eax, WORD PTR [esi+12] ecx, WORD PTR [esi+10] edx, WORD PTR [esi+8] eax eax, WORD PTR [esi+6] ecx ecx, WORD PTR [esi+2] edx edx, WORD PTR [esi] eax ecx edx OFFSET \$SG78594 _printf esi _free esp, 32</pre>
--	---

Again, we got the code cannot be distinguished from the previous one. And again it should be noted, you haven't to do this in practice, unless you really know what you are doing.

19.3 Fields packing in structure

One important thing is fields packing in structures⁴.

Let's take a simple example:

```
#include <stdio.h>
struct s
{
    char a;
    int b;
    char c;
    int d;
};
```

⁴See also: Wikipedia: Data structure alignment

```
void f(struct s s)
{
    printf ("a=%d; b=%d; c=%d; d=%d\n", s.a, s.b, s.c, s.d);
};
int main()
{
    struct s tmp;
    tmp.a=1;
    tmp.b=2;
    tmp.c=3;
    tmp.d=4;
    f(tmp);
};
```

As we see, we have two *char* fields (each is exactly one byte) and two more -int (each -4 bytes).

19.3.1 x86

This compiles to:

Listing 19.6: MSVC 2012 /GS- /Ob0

1	_tmp\$ = -1	6

We pass the structure as a whole, but in fact, as we can see, the structure is being copied to a temporary one (a place in stack is allocated in line 10 for it, and then all 4 fields, one by one, are copied in lines 12 ... 19), and then its pointer (address) is to be passed. The structure is copied because it's not known whether the f() function going to modify the structure or not. If it gets changed, then the structure in main() has to remain as it was. We could use C/C++ pointers, and the resulting code will be almost the same, but without the copying.

As we can see, each field's address is aligned on a 4-byte boundary. That's why each *char* occupies 4 bytes here (like *int*). Why? Because it is easier for the CPU to access memory at aligned addresses and to cache data from it.

However, it is not very economical.

Let's try to compile it with option (/Zp1) (/Zp[n] pack structures on n-byte boundary).

1	_main	PROC

```

Now the structure takes only 10 bytes and each *char* value takes 1 byte. What does it give to us? Size economy. And as drawback —the CPU accessing these fields slower than it could.

The structure is also copied in main(). Not field-by-field, but directly 10 bytes, using three pairs of MOV. Why not 4? The compiler decided that it's better to copy 10 bytes using 3 MOV pairs than to copy two 32-bit words and two bytes using 4

MOV pairs.

As it can be easily guessed, if the structure is used in many source and object files, all these must be compiled with the same convention about structures packing.

Aside from MSVC /Zp option which sets how to align each structure field, there is also the #pragma pack compiler option, which can be defined right in the source code. It is available in both MSVC⁵ and GCC⁶.

Let's get back to the SYSTEMTIME structure that consists of 16-bit fields. How does our compiler know to pack them on 1-byte alignment boundary?

WinNT.h file has this:

Listing 19.8: WinNT.h

#include "pshpack1.h"

And this:

Listing 19.9: WinNT.h

<pre>#include "pshpack4.h"</pre>	// 4 byte packing is ∠
\backsim the default	

The file PshPack1.h looks like:

Listing 19.10: PshPack1.h

This tell the compiler how to pack the structures defined after #pragma pack.

⁵MSDN: Working with Packing Structures

⁶Structure-Packing Pragmas

19.3.2 One more word

Passing a structure as a function argument (instead of a passing pointer to structure) is the same as passing all structure fields one by one. If the structure fields are packed by default, the f() function can be rewritten as:

```
void f(char a, int b, char c, int d)
{
    printf ("a=%d; b=%d; c=%d; d=%d\n", a, b, c, d);
};
```

And that leads to the same code.

19.4 Nested structures

Now what about situations when one structure is defined inside of another?

```
#include <stdio.h>
struct inner_struct
{
    int a:
    int b;
};
struct outer_struct
{
    char a;
    int b;
    struct inner struct c;
    char d;
    int e:
};
void f(struct outer struct s)
{
    printf ("a=%d; b=%d; c.a=%d; c.b=%d; d=%d; e=%d\n",
        s.a, s.b, s.c.a, s.c.b, s.d, s.e);
};
int main()
{
    struct outer struct s;
    s.a=1;
    s.b=2;
```

CHAPTER 19. STRUCTURES

```
s.c.a=100;
s.c.b=101;
s.d=3;
s.e=4;
f(s);
};
```

... in this case, both inner_struct fields are to be placed between the a,b and d,e fields of the outer_struct.

Let's compile (MSVC 2010):

Listing 19.11: Optimizing MSVC 2010 /Ob0

```
'a=%d; b=%d; c.a=%d; c.b=%d; d=%d; e=%d', OaH, O0∠

One curious thing here is that by looking onto this assembly code, we do not even see that another structure was used inside of it! Thus, we would say, nested structures are unfolded into *linear* or *one-dimensional* structure.

Of course, if we replace the struct inner_struct c; declaration with struct inner_struct *c; (thus making a pointer here) the situation will be quite different.

19.5 Bit fields in a structure

19.5.1 CPUID example

The C/C++ language allows to define the exact number of bits for each structure field. It is very useful if one needs to save memory space. For example, one bit is enough for a *bool* variable. But of course, it is not rational if speed is important.

Let's consider the CPUID⁷ instruction example. This instruction returns information about the current CPU and its features.

If the EAX is set to 1 before the instruction's execution, CPUID returning this information packed into the EAX register:

⁷wikipedia

3:0 (4 bits)	Stepping
7:4 (4 bits)	Model
11:8 (4 bits)	Family
13:12 (2 bits)	Processor Type
19:16 (4 bits)	Extended Model
27:20 (8 bits)	Extended Family

MSVC 2010 has CPUID macro, but GCC 4.4.1 does not. So let's make this function by ourselves for GCC with the help of its built-in assembler⁸.

```
#include <stdio.h>
#ifdef GNUC
static inline void cpuid(int code, int *a, int *b, int *c, int 2
    ⊊ *d) {
  asm volatile("cpuid":"=a"(*a),"=b"(*b),"=c"(*c),"=d"(*d):"a"(2
    \u00e3 code)):
}
#endif
#ifdef _MSC_VER
#include <intrin.h>
#endif
struct CPUID 1 EAX
{
    unsigned int stepping:4;
    unsigned int model:4;
    unsigned int family_id:4;
    unsigned int processor_type:2;
    unsigned int reserved1:2;
    unsigned int extended model id:4;
    unsigned int extended family id:8;
    unsigned int reserved2:4;
};
int main()
{
    struct CPUID_1_EAX *tmp;
    int b[4];
#ifdef _MSC_VER
     __cpuid(b,1);
#endif
#ifdef GNUC
```

⁸More about internal GCC assembler

After CPUID fills EAX/EBX/ECX/EDX, these registers are to be written in the b[] array. Then, we have a pointer to the CPUID_1_EAX structure and we point it to the value in EAX from the b[] array.

In other words, we treat a 32-bit *int* value as a structure. Then we read specific bits from the structure.

MSVC

Let's compile it in MSVC 2008 with /Ox option:

Listing	19.12: 0)ptimizing	MSVC	2008

```
b$ = -16 : size = 16
         PROC
main
           esp, 16
    sub
   push

         edx, esi
          edx, 8
   shr
   and
         edx, 15
         edx
   push
          OFFSET $SG15437 ; 'family_id=%d', OaH, OOH
   push
   call
          _printf
   mov
         eax, esi
   shr
          eax, 12
   and
          eax, 3
   push
          eax
          OFFSET $SG15438 ; 'processor_type=%d', OaH, OOH
   push
   call
          printf
          ecx, esi
   mov
   shr
          ecx, 16
   and
         ecx, 15
   push
         ecx
          OFFSET $SG15439 ; 'extended_model_id=%d', OaH, OOH
   push
   call
          printf
   shr
         esi. 20
          esi, 255
   and
   push
         esi
   push OFFSET $SG15440 ; 'extended_family_id=%d', 0aH, 00H
   call
          _printf
   add
          esp, 48
   pop
          esi
         eax, eax
   xor
          ebx
   pop
   add
          esp, 16
   ret
          0
        ENDP
main
```

The SHR instruction shifting the value in EAX by the number of bits that must be *skipped*, e.g., we ignore some bits *at the right side*.

The AND instruction clears the unneeded bits *on the left*, or, in other words, leaves only those bits in the EAX register we need.

Chapter 20

64-bit values in 32-bit environment

20.1 Returning of 64-bit value

20.1.1 x86

In a 32-bit environment, 64-bit values are returned from functions in the EDX:EAX register pair.

Listing 20.1:	Optimizing	MSVC 2010	
---------------	------------	-----------	--

_f	PROC					
	mov	eax,	-1867788817	;	90abcdefH	
	mov	edx,	305419896	;	12345678H	
	ret	0				
_f	ENDP					
-						

20.2 Arguments passing, addition, subtraction

```
#include <stdint.h>
uint64_t f_add (uint64_t a, uint64_t b)
{
       return a+b;
};
void f_add_test ()
{
#ifdef __GNUC_
       printf ("%lld\n", f_add(12345678901234, 23456789012345) 2
   \, );
#else
       printf ("%I64d\n", f_add(12345678901234, ∠
   #endif
};
uint64 t f sub (uint64 t a, uint64 t b)
{
       return a-b;
};
```

20.2.1 x86

Listing 20.2: Optimizing MSVC 2012 /Ob1

_a\$ = 8 b\$ = 16		; size = 8 ; size = 8	
—	PROC	,	
	mov	eax, DWORD	PTR _a\$[esp-4]

	push		; 00000b3aH
	push	1942892530	; 73ce2ff_subH
	call	_f_add	

ם. סוג סוג סוג סוג סוג סוג סוג סוג סוג סוג	ush edx ush eax ush OFFSE all _prir dd esp, et 0 st ENDP	ntf	; '%I64d',	0aH, 00H
ma su ma sł	ub eax, ov edx,	DWORD PTR DWORD PTR DWORD PTR DWORD PTR	_b\$[esp-4] _a\$[esp]	

We can see in the f_add_test() function that each 64-bit value is passed using two 32-bit values, high part first, then low part.

Addition and subtraction occur in pairs as well.

In addition, the low 32-bit part are added first. If carry was occurred while adding, the CF flag is set. The following ADC instruction adds the high parts of the values, and also adds 1 if CF = 1.

Subtraction also occurs in pairs. The first SUB may also turn on the CF flag, which is to be checked in the subsequent SBB instruction: if the carry flag is on, then 1 is also to be subtracted from the result.

It is easy to see how the f_add() function result is then passed to printf().

20.3 Multiplication, division

```
#include <stdint.h>
uint64_t f_mul (uint64_t a, uint64_t b)
{
        return a*b;
};
uint64_t f_div (uint64_t a, uint64_t b)
{
        return a/b;
};
```

```
uint64_t f_rem (uint64_t a, uint64_t b)
{
     return a % b;
};
```

20.3.1 x86

Listing 20.3: Optimizing MSVC 2013 /Ob1

```
_a$ = 8 ; size = 8
b$ = 16 ; size = 8
_f_mul
        PROC
        push
                ebp
        mov
                ebp, esp
        mov
                eax, DWORD PTR _b$[ebp+4]
        push
                eax
        mov
                ecx, DWORD PTR _b$[ebp]
        push
                ecx
        mov
                edx, DWORD PTR a$[ebp+4]
                edx
        push
                eax, DWORD PTR a$[ebp]
        mov
        push
                eax
        call
                __allmul ; long long multiplication
        pop
                ebp
                0
        ret
f mul
        ENDP
a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_f_div
        PROC
        push
                ebp
        mov
                ebp, esp
        mov
                eax, DWORD PTR _b$[ebp+4]
        push
                eax
        mov
                ecx, DWORD PTR _b$[ebp]
        push
                ecx
        mov
                edx, DWORD PTR a$[ebp+4]
        push
                edx
        mov
                eax, DWORD PTR _a$[ebp]
        push
                eax
        call
                  _aulldiv ; unsigned long long division
        pop
                ebp
                0
        ret
_f_div
        ENDP
```

```
a$ = 8 ; size = 8
b$ = 16 ; size = 8
       PROC
frem
                ebp
        push
                ebp, esp
        mov
                eax, DWORD PTR _b$[ebp+4]
        mov
        push
                eax
                ecx, DWORD PTR _b$[ebp]
        mov
        push
                ecx
        mov
                edx, DWORD PTR _a$[ebp+4]
        push
                edx
        mov
                eax, DWORD PTR a$[ebp]
        push
                eax
        call
                __aullrem ; unsigned long long remainder
        pop
                ebp
                0
        ret
_f_rem
       ENDP
```

Multiplication and division are more complex operations, so usually the compiler embeds calls to a library functions doing that.

20.4 Shifting right

20.4.1 x86

Listing 20.4: Optimizing MSVC 2012 /Ob1

```
_a$ = 8
                 ; size = 8
f
        PROC
                 eax, DWORD PTR _a$[esp-4]
        mov
                 edx, DWORD PTR _a$[esp]
        mov
        shrd
                 eax, edx, 7
                 edx, 7
        shr
        ret
                 0
f
        FNDP
```

Shifting also occurs in two passes: first the lower part is shifted, then the higher part. But the lower part is shifted with the help of the SHRD instruction, it shifts the value of EDX by 7 bits, but pulls new bits from EAX, i.e., from the higher part. The higher part is shifted using the more popular SHR instruction: indeed, the freed bits in the higher part must be filled with zeroes.

20.5 Converting 32-bit value into 64-bit one

20.5.1 x86

Listina	20 5.	Ontimizina	MSVC 2012
LISUNG	20.5.	optimizing	

_a\$ = 8	3	
_f	PROC	
	mov	eax, DWORD PTR _a\$[esp-4]
	cdq	
	ret	0
_f	ENDP	

Here we also run into necessity to extend a 32-bit signed value into a 64-bit signed one. Unsigned values are converted straightforwardly: all bits in the higher part must be set to 0. But this is not appropriate for signed data types: the sign has to be copied into the higher part of the resulting number. The CDQ instruction does that here, it takes its input value in EAX, extends it to 64-bit and leaves it in the EDX:EAX register pair. In other words, CDQ gets the number sign from EAX (by getting the most significant bit in EAX), and depending of it, sets all 32 bits in EDX to 0 or 1. Its operation is somewhat similar to the MOVSX instruction.

Chapter 21

64 bits

21.1 x86-64

It is a 64-bit extension to the x86 architecture.

From the reverse engineer's perspective, the most important changes are:

• Almost all registers (except FPU and SIMD) were extended to 64 bits and got a R- prefix. 8 additional registers wer added. Now GPR's are: RAX, RBX, RCX, RDX, RBP, RSP, RSI, RDI, R8, R9, R10, R11, R12, R13, R14, R15.

It is still possible to access the *older* register parts as usual. For example, it is possible to access the lower 32-bit part of the RAX register using EAX:

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RAX ^{x64}							
					E	ĄХ	
						ŀ	٩X
						AH	AL

The new R8-R15 registers also have their *lower parts*: R8D-R15D (lower 32-bit parts), R8W-R15W (lower 16-bit parts), R8L-R15L (lower 8-bit parts).

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R8							
					R	8D	
						R	8W
							R8L

The number of SIMD registers was doubled from 8 to 16: XMM0-XMM15.

• In Win64, the function calling convention is slightly different, somewhat resembling fastcall. The first 4 arguments are stored in the RCX, RDX, R8, R9 registers, the rest —in the stack. The caller function must also allocate 32 bytes so the callee may save there 4 first arguments and use these registers for its own needs. Short functions may use arguments just from registers, but larger ones may save their values on the stack.

System V AMD64 ABI (Linux, *BSD, Mac OS X)[Mit13] also somewhat resembles fastcall, it uses 6 registers RDI, RSI, RDX, RCX, R8, R9 for the first 6 arguments. All the rest are passed via the stack.

- The C/C++ *int* type is still 32-bit for compatibility.
- All pointers are 64-bit now.

This provokes irritation sometimes: now one needs twice as much memory for storing pointers, including cache memory, despite the fact that x64 CPUs can address only 48 bits of external RAM¹.

Since now the number of registers is doubled, the compilers have more space for maneuvering called register allocation. For us this implies that the emitted code containing less number of local variables.

By the way, there are CPUs with much more GPR's, e.g. Itanium (128 registers).

¹Random-access memory

Part II

Important fundamentals

Chapter 22

Signed number representations

There are several methods for representing signed numbers¹, but "two's complement" is the most popular one in computers.

Here is a table for some byte values:

binary	hexadecimal	unsigned	signed (2's complement)
01111111	0x7f	127	127
01111110	0x7e	126	126
00000110	0x6	6	6
00000101	0x5	5	5
00000100	0x4	4	4
00000011	0x3	3	3
00000010	0x2	2	2
0000001	0x1	1	1
00000000	0x0	0	0
11111111	0xff	255	-1
11111110	0xfe	254	-2
11111101	0xfd	253	-3
11111100	0xfc	252	-4
11111011	0xfb	251	-5
11111010	Oxfa	250	-6
		•••	
10000010	0x82	130	-126
10000001	0x81	129	-127
1000000	0x80	128	-128

¹wikipedia

The difference between signed and unsigned numbers is that if we represent $0 \times FFFFFFE$ and 0×0000002 as unsigned, then the first number (4294967294) is bigger than the second one (2). If we represent them both as signed, the first one is to be -2, and it is smaller than the second (2). That is the reason why conditional jumps (11 on page 50) are present both for signed (e.g. JG, JL) and unsigned (JA, JB) operations.

For the sake of simplicity, that is what one need to know:

- Numbers can be signed or unsigned.
- C/C++ signed types:
 - int64_t (-9,223,372,036,854,775,808..9,223,372,036,854,775,807) (-9.2..9.2 quintillions) or 0x8000000000000000..0x7FFFFFFFFFFFFFFFFF,
 - int (-2,147,483,648..2,147,483,647 (- 2.15.. 2.15Gb) or 0x80000000..0x7FFFF
 - *char* (-128..127 or 0x80..0x7F),
 - ssize_t.

Unsigned:

- uint64_t (0..18,446,744,073,709,551,615 (18 quintillions) or 0..0xFFFFFFF
- unsigned int (0..4,294,967,295 (4.3Gb) or 0..0xFFFFFFF),
- unsigned char (0..255 or 0..0xFF),
- size_t.
- Signed types have the sign in the most significant bit: 1 mean "minus", 0 mean "plus".
- Promoting to a larger data types is simple: 20.5 on page 152.
- Negation is simple: just invert all bits and add 1. We can remember that a number of inverse sign is located on the opposite side at the same proximity from zero. The addition of one is needed because zero is present in the middle.
- The addition and subtraction operations work well for both signed and unsigned values. But for multiplication and division operations, x86 has different instructions: IDIV/IMUL for signed and DIV/MUL for unsigned.

Chapter 23

Memory

There are 3 main types of memory:

- Global memory. AKA "static memory allocation". No need to allocate explicitly, the allocation is done just by declaring variables/arrays globally. These are global variables, residing in the data or constant segments. The are available globally (hence, considered as an anti-pattern). Not convenient for buffers/arrays, because they must have a fixed size. Buffer overflows that occur here usually overwrite variables or buffers reside next to them in memory. There's an example in this book: 7.2 on page 30.
- Stack. AKA "allocate on stack". The allocation is done just by declaring variables/arrays locally in the function. These are usually local variables for the function. Sometimes these local variable are also available to descending functions (to callee functions, if caller passes a pointer to a variable to the callee to be executed). Allocation and deallocation are very fast, it's just SP needs to be shifted. But they're also not convenient for buffers/arrays, because the buffer size has to be fixed, unless alloca() (5.2.4 on page 17) (or a variable-length array) is used. Buffer overflows usually overwrite important stack structures: 16.2 on page 95.
- Heap. AKA "dynamic memory allocation". Allocation is done by calling malloc()/free() or new/delete in C++. This is the most convenient method: the block size may be set at runtime. Resizing is possible (using realloc()), but can be slow. This is the slowest way to allocate memory: the memory allocator must support and update all control structures while allocating and deallocating. Buffer overflows usually overwrite these structures. Heap allocations are also source of memory leak problems: each memory block has to be deallocated explicitly, but one may forget about it, or do it incorrectly. Another problem is the "use after free"–using a memory block after free()

was called on it, which is very dangerous. Example in this book: 19.2 on page 132.

Part III

Finding important/interesting stuff in the code

Minimalism it is not a prominent feature of modern software.

But not because the programmers are writing a lot, but because a lot of libraries are commonly linked statically to executable files. If all external libraries were shifted into an external DLL files, the world would be different. (Another reason for C++ are the STL and other template libraries.)

Thus, it is very important to determine the origin of a function, if it is from standard library or well-known library (like Boost¹, libpng²), or if it is related to what we are trying to find in the code.

It is just absurd to rewrite all code in C/C++ to find what we're looking for.

One of the primary tasks of a reverse engineer is to find quickly the code he/she needs.

The IDA disassembler allow us to search among text strings, byte sequences and constants. It is even possible to export the code to .lst or .asm text files and then use grep, awk, etc.

When you try to understand what some code is doing, this easily could be some open-source library like libpng. So when you see some constants or text strings which look familiar, it is always worth to *google* them. And if you find the open-source project where they are used, then it's enough just to compare the functions. It may solve some part of the problem.

For example, if a program uses XML files, the first step may be determining which XML library is used for processing, since the standard (or well-known) libraries are usually used instead of self-made one.

For example, author of these lines once tried to understand how the compression/decompression of network packets worked in SAP 6.0. It is a huge software, but a detailed .PDB with debugging information is present, and that is convenient. He finally came to the idea that one of the functions, that was called CsDecomprLZC, was doing the decompression of network packets. Immediately he tried to google its name and he quickly found the function was used in MaxDB (it is an open-source SAP project).

http://www.google.com/search?q=CsDecomprLZC

Astoundingly, MaxDB and SAP 6.0 software shared likewise code for the compression/decompression of network packets.

¹http://go.yurichev.com/17036

²http://go.yurichev.com/17037

Chapter 24

Communication with the outer world (win32)

Sometimes it's enough to observe some function's inputs and outputs in order to understand what it does. That way you can save time.

Files and registry access: for the very basic analysis, Process Monitor¹ utility from SysInternals can help.

For the basic analysis of network accesses, Wireshark² can be useful.

But then you will have to to look inside anyway.

The first thing to look for is which functions from the OS's API³s and standard libraries are used.

If the program is divided into a main executable file and a group of DLL files, sometimes the names of the functions in these DLLs can help.

If we are interested in exactly what can lead to a call to MessageBox() with specific text, we can try to find this text in the data segment, find the references to it and find the points from which the control may be passed to the MessageBox() call we're interested in.

If we are talking about a video game and we're interested in which events are more or less random in it, we may try to find the rand() function or its replacements (like the Mersenne twister algorithm) and find the places from which those functions are called, and more importantly, how are the results used.

²http://go.yurichev.com/17303

¹http://go.yurichev.com/17301

³Application programming interface

But if it is not a game, and rand() is still used, it is also interesting to know why. There are cases of unexpected rand() usage in data compression algorithms (for encryption imitation): blog.yurichev.com.

24.1 Often used functions in the Windows API

These functions may be among the imported. It is worth to note that not every function might be used in the code that was written by the programmer. A lot of functions might be called from library functions and CRT code.

- Registry access (advapi32.dll): RegEnumKeyEx^{4 5}, RegEnumValue^{6 5}, RegGet-Value^{7 5}, RegOpenKeyEx^{8 5}, RegQueryValueEx^{9 5}.
- Access to text .ini-files (kernel32.dll): GetPrivateProfileString ^{10 5}.
- Dialog boxes (user32.dll): MessageBox ^{11 5}, MessageBoxEx ^{12 5}, SetDlgItem-Text ^{13 5}, GetDlgItemText ^{14 5}.
- Resources access : (user32.dll): LoadMenu ^{15 5}.
- TCP/IP networking (ws2_32.dll): WSARecv ¹⁶, WSASend ¹⁷.
- File access (kernel32.dll): CreateFile ^{18 5}, ReadFile ¹⁹, ReadFileEx ²⁰, WriteFile ²¹, WriteFileEx ²².
- High-level access to the Internet (wininet.dll): WinHttpOpen ²³.

- Checking the digital signature of an executable file (wintrust.dll): WinVerifyTrust ²⁴.
- The standard MSVC library (if it's linked dynamically) (msvcr*dll): assert, itoa, ltoa, open, printf, read, strcmp, atol, atoi, fopen, fread, fwrite, memcmp, rand, strlen, strstr, strchr.

24.2 tracer: Intercepting all functions in specific module

There are INT3 breakpoints in the tracer, that are triggered only once, however, they can be set for all functions in a specific DLL.

--one-time-INT3-bp:somedll.dll!.*

Or, let's set INT3 breakpoints on all functions with the xml prefix in their name:

--one-time-INT3-bp:somedll.dll!xml.*

On the other side of the coin, such breakpoints are triggered only once.

Tracer will show the call of a function, if it happens, but only once. Another drawback it is impossible to see the function's arguments.

Nevertheless, this feature is very useful when you know that the program uses a DLL, but you do not know which functions are actually used. And there are a lot of functions.

For example, let's see, what does the uptime utility from cygwin use:

tracer -l:uptime.exe --one-time-INT3-bp:cygwin1.dll!.*

Thus we may see all that cygwin1.dll library functions that were called at least once, and where from:

Strings

25.1 Text strings

25.1.1 C/C++

The normal C strings are zero-terminated (ASCIIZ-strings).

The reason why the C string format is as it is (zero-terminated) is apparently historical. In [Rit79] we read:

A minor difference was that the unit of I/O was the word, not the byte, because the PDP-7 was a word-addressed machine. In practice this meant merely that all programs dealing with character streams ignored null characters, because null was used to pad a file to an even number of characters.

In Hiew or FAR Manager these strings looks like this:

📑 н	iew: h	w1.exe										
	C:\	Polygor	ı\hw	1.ex	e					₽FRC)	
He	110,	world!	3 p	√@	F	o√@ [22			Ð		
	Ð	Ð	Ð	Ð	P	P	P	Ð	P	P	Ð	₽
5	ы	1	5	151	Δ.		C	5	D	ы	R	

Figure 25.1: Hiew

25.1.2 Borland Delphi

The string in Pascal and Borland Delphi is preceded by an 8-bit or 32-bit string length.

For example:

```
      Listing 25.1: Delphi

      CODE:00518AC8
      dd 19h

      CODE:00518ACC aLoading_Plea
      db 'Loading..., please wait.',0

      ...
      CODE:00518AFC

      CODE:00518AFC
      dd 10h

      CODE:00518B00 aPreparingRun_
      db 'Preparing run...',0
```

25.1.3 Unicode

Often, what is called Unicode is a methods for encoding strings where each character occupies 2 bytes or 16 bits. This is a common terminological mistake. Unicode is a standard for assigning a number to each character in the many writing systems of the world, but does not describe the encoding method.

The most popular encoding methods are: UTF-8 (is widespread in Internet and *NIX systems) and UTF-16LE (is used in Windows).

UTF-8

UTF-8 is one of the most successful methods for encoding characters. All Latin symbols are encoded just like in ASCII, and the symbols beyond the ASCII table are encoded using several bytes. 0 is encoded as before, so all standard C string functions work with UTF-8 strings just like any other string.

Let's see how the symbols in various languages are encoded in UTF-8 and how it looks like in FAR, using the 437 codepage ¹:

```
How much? 100€?
```

(English) I can eat glass and it doesn't hurt me.
(Greek) Μπορώ να φάω σπασμένα γυαλιά χωρίς να πάθω τίποτα.
(Hungarian) Meg tudom enni az üveget, nem lesz tőle bajom.
(Icelandic) Ég get etið gler án þess að meiða mig.
(Polish) Mogę jeść szkło i mi nie szkodzi.
(Russian) Я могу есть стекло, оно мне не вредит.
(Arabic): أنا قادر على أكل الزجاع و هذا لا يؤلمني.
(Hebrew): أنا قادر على أكل الزجاع و هذا لا يؤلمني.
(Chinese) 我能吞下玻璃而不伤身体。
(Japanese) 私はガラスを食べられます。それは私を傷つけません。
(Hindi) 并 काँच खा सकता हँ और मुझे उससे कोई चोट नहीं पहंचती.

view hw4_UTF8.txt - Far 3.0.4040 x64 Administrator –
w4_UTF8.txt t 437 872 col 0 100%
דבר How much? 100ré%?
(English) I can eat glass and it doesn't hurt me. (Greek) #£±ζ∰_±ü±Ä #J#∰ ±ä#¼±ë ±ä±ζ∰±ä#J#1#J#∰ # ±ä#∰#ŋ#¶#¼ ±ζ±ë±ü#»±é #J#∰ ±ζ#¼#ŋ±ë ±ä#»±ζ#ŋ± (Hungarian) Meg tudom enni az jJveget, nem lesz t+æle bajom. (Icelandic) jeg get etij≣ gler jin jJess al≞ meij∰ mig. (Polish) Mog-Ö jefq-ç szkłėo i mi nie szkodzi. (Russian) J» JJJJJ ja JJjjjjjjjjjjjjjjjjjjjjjjjjj

Figure 25.2: FAR: UTF-8

As you can see, the English language string looks the same as it is in ASCII. The Hungarian language uses some Latin symbols plus symbols with diacritic marks. These symbols are encoded using several bytes, these are underscored with red. It's the same story with the Icelandic and Polish languages. There is also the "Euro"

¹The example and translations was taken from here: http://go.yurichev.com/17304

currency symbol at the start, which is encoded with 3 bytes. The rest of the writing systems here have no connection with Latin. At least in Russian, Arabic, Hebrew and Hindi we can see some recurring bytes, and that is not surprise: all symbols from a writing system are usually located in the same Unicode table, so their code begins with the same numbers.

At the beginning, before the "How much?" string we see 3 bytes, which are in fact the BOM^2 . The BOM defines the encoding system to be used.

UTF-16LE

Many win32 functions in Windows have the suffixes -A and -W. The first type of functions works with normal strings, the other with UTF-16LE strings (*wide*). In the second case, each symbol is usually stored in a 16-bit value of type *short*.

The Latin symbols in UTF-16 strings look in Hiew or FAR like they are interleaved with zero byte:

```
int wmain()
{
     wprintf (L"Hello, world!\n");
};
```

E H	liew:	hw2.e>	œ									
	C :	\Pol	ygon\	hw2	.exe						₽FRO	
Η	el	1 o 2	, II 2	101	• 1 d	11			¤@		¤@ ₽	2
2	2	2	2	[!	9 0	9 5	2	₽ A	P	₽ C	2	

Figure 25.3: Hiew

We can see this often in Windows NT system files:

²Byte order mark

	vie	wr	ito	skr	nL	exe	e - I	Far	2.0).1	807	/ x(54 /	Adı	nir	iist	rat	or

Figure 25.4: Hiew

Strings with characters that occupy exactly 2 bytes are called "Unicode" in IDA:

.data:0040E000 aHelloWorld:	
.data:0040E000	unicode 0, <hello, world!=""></hello,>
.data:0040E000	dw OAh, O

Here is how the Russian language string is encoded in UTF-16LE:

Figure 25.5: Hiew: UTF-16LE

What we can easily spot is that the symbols are interleaved by the diamond character (which has the ASCII code of 4). Indeed, the Cyrillic symbols are located in the fourth Unicode plane ³. Hence, all Cyrillic symbols in UTF-16LE are located in the 0x400-0x4FF range.

³wikipedia

Let's go back to the example with the string written in multiple languages. Here is how it looks like in UTF-16LE.

88			viow bw		.txt - Far 3.0.	1040 264 4	dministrator			_ 0

Figure 25.6: FAR: UTF-16LE

Here we can also see the BOM in the beginning. All Latin characters are interleaved with a zero byte. Some characters with diacritic marks (Hungarian and Icelandic languages) are also underscored in red.

25.1.4 Base64

The base64 encoding is highly popular for the cases when you need to transfer binary data as a text string. In essence, this algorithm encodes 3 binary bytes into 4 printable characters: all 26 Latin letters (both lower and upper case), digits, plus sign ("+") and slash sign ("/"), 64 characters in total.

One distinctive feature of base64 strings is that they often (but not always) ends with 1 or 2 padding equality symbol(s) ("="), for example:

The equality sign ("=") is never encounter in the middle of base64-encoded strings.

25.2 Error/debug messages

Debugging messages are very helpful if present. In some sense, the debugging messages are reporting what's going on in the program right now. Often these are printf()-like functions, which write to log-files, or sometimes do not writing anything but the calls are still present since the build is not a debug one but *release* one. If local or global variables are dumped in debug messages, it might be helpful as well since it is possible to get at least the variable names. For example, one of such function in Oracle RDBMS is ksdwrt().

Meaningful text strings are often helpful. The IDA disassembler may show from which function and from which point this specific string is used. Funny cases sometimes happen⁴.

The error messages may help us as well. In Oracle RDBMS, errors are reported using a group of functions.

You can read more about them here: blog.yurichev.com.

It is possible to find quickly which functions report errors and in which conditions. By the way, this is often the reason for copy-protection systems to inarticulate cryptic error messages or just error numbers. No one is happy when the software cracker quickly understand why the copy-protection is triggered just by the error message.

25.3 Suspicious magic strings

Some magic strings which are usually used in backdoors looks pretty suspicious. For example, there was a backdoor in the TP-Link WR740 home router⁵. The backdoor was activated using the following URL:

http://192.168.0.1/userRpmNatDebugRpm26525557/start_art.html. Indeed, the "userRpmNatDebugRpm26525557" string is present in the firmware. This string was not googleable until the wide disclosure of information about the backdoor. You would not find this in any RFC⁶. You would not find any computer

⁴blog.yurichev.com

⁵http://sekurak.pl/tp-link-httptftp-backdoor/

⁶Request for Comments

science algorithm which uses such strange byte sequences. And it doesn't look like an error or debugging message. So it's a good idea to inspect the usage of such weird strings.

Sometimes, such strings are encoded using base64. So it's a good idea to decode them all and to scan them visually, even a glance should be enough.

More precise, this method of hiding backdoors is called "security through obscurity".

Calls to assert()

Sometimes the presence of the assert() macro is useful too: commonly this macro leaves source file name, line number and condition in the code.

The most useful information is contained in the assert's condition, we can deduce variable names or structure field names from it. Another useful piece of information are the file names—we can try to deduce what type of code is there. Also it is possible to recognize well-known open-source libraries by the file names.

Listing 26.1: Example of informative assert() calls

```
.text:107D4B29 mov
                    dx, [ecx+42h]
.text:107D4B2D cmp
                    edx, 1
.text:107D4B30 jz
                    short loc 107D4B4A
.text:107D4B32 push 1ECh
.text:107D4B37 push offset aWrite_c ; "write.c"
.text:107D4B3C push offset aTdTd_planarcon ; "td->√
   └ td planarconfig == PLANARCONFIG CON"...
.text:107D4B41 call ds:_assert
. . .
                    edx, [ebp-4]
.text:107D52CA mov
.text:107D52CD and
                    edx, 3
.text:107D52D0 test edx, edx
.text:107D52D2 jz
                    short loc_107D52E9
.text:107D52D4 push 58h
.text:107D52D6 push offset aDumpmode c ; "dumpmode.c"
                                  ; "(n & 3) == 0"
.text:107D52DB push offset aN30
.text:107D52E0 call ds: assert
```

It is advisable to "google" both the conditions and file names, which can lead us to an open-source library. For example, if we "google" "sp->lzw_nbits <= BITS_MAX", this predictably gives us some open-source code that's related to the LZW compression.

Constants

Humans, including programmers, often use round numbers like 10, 100, 1000, in real life as well as in the code.

The practicing reverse engineer usually know them well in hexadecimal representation: 10=0xA, 100=0x64, 1000=0x3E8, 10000=0x2710.

Some algorithms, especially cryptographical ones use distinct constants, which are easy to find in code using IDA.

For example, the MD5³ algorithm initializes its own internal variables like this:

var int h0 := 0x67452301
var int h1 := 0xEFCDAB89
var int h2 := 0x98BADCFE
var int h3 := 0x10325476

If you find these four constants used in the code in a row, it is very highly probable that this function is related to MD5.

Another example are the CRC16/CRC32 algorithms, whose calculation algorithms often use precomputed tables like this one:

¹Master Boot Record

²Read-only memory

³wikipedia

			=			020.0		
/**		C table fo		RC-16. TH	ne poly i	is 0x800	5 (x^16 -	+ x^15 +∠

	4	0x0E40,						

Listing 271. linux/lib/crc16 c

27.1 Magic numbers

A lot of file formats define a standard file header where a *magic number(s)*⁴ is used, single one or even several.

For example, all Win32 and MS-DOS executables start with the two characters "MZ"⁵.

At the beginning of a MIDI file the "MThd" signature must be present. If we have a program which uses MIDI files for something, it's very likely that it must check the file for validity by checking at least the first 4 bytes.

This could be done like this:

(buf points to the beginning of the loaded file in memory)

```
cmp [buf], 0x6468544D ; "MThd"
jnz _error_not_a_MIDI_file
```

... or by calling a function for comparing memory blocks like memcmp() or any other equivalent code up to a CMPSB instruction.

When you find such point you already can say where the loading of the MIDI file starts, also, we could see the location of the buffer with the contents of the MIDI file, what is used from the buffer, and how.

27.1.1 DHCP

This applies to network protocols as well. For example, the DHCP protocol's network packets contains the so-called *magic cookie*: 0x63538263. Any code that

⁴wikipedia

⁵wikipedia

generates DHCP packets somewhere must embed this constant into the packet. If we find it in the code we may find where this happens and, not only that. Any program which can receive DHCP packet must verify the *magic cookie*, comparing it with the constant.

For example, let's take the dhcpcore.dll file from Windows 7 x64 and search for the constant. And we can find it, twice: it seems that the constant is used in two functions with descriptive names like DhcpExtractOptionsForValidation() and DhcpExtractFullOptions():

Listing 27.2: dhcpcore.dll (Windows 7 x64)

.rdata:000007FF6483CBE8 dword_7FF6483CBE8 dd 63538263h	2
<pre>、 ; DATA XREF: DhcpExtractOptionsForValidation+79</pre>	
.rdata:000007FF6483CBEC dword_7FF6483CBEC dd 63538263h	2
🦕 ; DATA XREF: DhcpExtractFullOptions+97	

And here are the places where these constants are accessed:

Listing 27.3: dhcpcore.dll (Windows 7 x64)

.text:000007FF6480875F	mov	eax, [rsi]
.text:000007FF64808761	cmp	eax, cs:dword_7FF6483CBE8
.text:000007FF64808767	jnz	loc_7FF64817179

And:

Listing 27.4: dhcpcore.dll (Windows 7 x64)

.text:000007FF648082C7 .text:000007FF648082CB .text:000007FF648082D1	cmp	eax, [r12] eax, cs:dword_7FF6483CBEC loc 7FF648173AF
. LEXT. 00000711048082D1	2112	100_71104017581

27.2 Searching for constants

It is easy in IDA: Alt-B or Alt-I. And for searching for a constant in a big pile of files, or for searching in non-executable files, there is a small utility called *binary grep*⁶.

Finding the right instructions

If the program is utilizing FPU instructions and there are very few of them in the code, one can try to check each one manually with a debugger.

For example, we may be interested how Microsoft Excel calculates the formulae entered by user. For example, the division operation.

If we load excel.exe (from Office 2010) version 14.0.4756.1000 into IDA, make a full listing and to find every FDIV instruction (except the ones which use constants as a second operand—obviously, they do not suit us):

cat EXCEL.lst | grep fdiv | grep -v dbl_ > EXCEL.fdiv

...then we see that there are 144 of them.

We can enter a string like =(1/3) in Excel and check each instruction.

By checking each instruction in a debugger or tracer (one may check 4 instruction at a time), we get lucky and the sought-for instruction is just the 14th:

.text:3	011E9 ⁻	19 DC	33
∽ q	word p	ptr [ebx]

fdiv

2

```
PID=13944|TID=28744|(0) 0x2f64e919 (Excel.exe!BASE+0x11e919)
EAX=0x02088006 EBX=0x02088018 ECX=0x00000001 EDX=0x00000001
ESI=0x02088000 EDI=0x00544804 EBP=0x0274FA3C ESP=0x0274F9F8
EIP=0x2F64E919
FLAGS=PF IF
FPU ControlWord=IC RC=NEAR PC=64bits PM UM OM ZM DM IM
```

FPU StatusWord=
FPU ST(0): 1.000000

ST(0) holds the first argument (1) and second one is in [EBX].

The instruction after FDIV (FSTP) writes the result in memory:

.text:3011E91B DD 1E fstp ∠ \, qword ptr [esi]

If we set a breakpoint on it, we can see the result:

PID=32852|TID=36488|(0) 0x2f40e91b (Excel.exe!BASE+0x11e91b) EAX=0x00598006 EBX=0x00598018 ECX=0x00000001 EDX=0x00000001 ESI=0x00598000 EDI=0x00294804 EBP=0x026CF93C ESP=0x026CF8F8 EIP=0x2F40E91B FLAGS=PF IF FPU ControlWord=IC RC=NEAR PC=64bits PM UM OM ZM DM IM FPU StatusWord=C1 P FPU ST(0): 0.333333

Also as a practical joke, we can modify it on the fly:

tracer -l:excel.exe bpx=excel.exe!BASE+0x11E91B,set(st0,666)

```
PID=36540|TID=24056|(0) 0x2f40e91b (Excel.exe!BASE+0x11e91b)
EAX=0x00680006 EBX=0x00680018 ECX=0x00000001 EDX=0x00000001
ESI=0x00680000 EDI=0x00395404 EBP=0x0290FD9C ESP=0x0290FD58
EIP=0x2F40E91B
FLAGS=PF IF
FPU ControlWord=IC RC=NEAR PC=64bits PM UM OM ZM DM IM
FPU StatusWord=C1 P
FPU ST(0): 0.333333
Set ST0 register to 666.000000
```

Excel shows 666 in the cell, finally convincing us that we have found the right point.

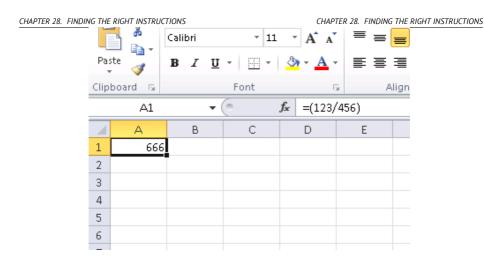

Figure 28.1: The practical joke worked

If we try the same Excel version, but in x64, we will find only 12 FDIV instructions there, and the one we looking for is the third one.

It seems that a lot of division operations of *float* and *double* types, were replaced by the compiler with SSE instructions like DIVSD (DIVSD is present 268 times in total).

Suspicious code patterns

29.1 XOR instructions

Instructions like XOR op, op (for example, XOR EAX, EAX) are usually used for setting the register value to zero, but if the operands are different, the "exclusive or" operation is executed. This operation is rare in common programming, but widespread in cryptography, including amateur one. It's especially suspicious if the second operand is a big number. This may point to encrypting/decrypting, checksum computing,etc.

This AWK script can be used for processing IDA listing (.lst) files:

29.2 Hand-written assembly code

Modern compilers do not emit the LOOP and RCL instructions. On the other hand, these instructions are well-known to coders who like to code directly in assembly language. If you spot these, it can be said that there is a high probability that this fragment of code was hand-written.

Also the function prologue/epilogue are not commonly present in hand-written assembly.

Commonly there is no fixed system for passing arguments to functions in the handwritten code.

Example from the Windows 2003 kernel (ntoskrnl.exe file):

```
MultiplyTest proc near
                                      : CODE XREF: ∠
    └→ Get386Stepping
             xor
                     cx, cx
loc 620555:
                                      ; CODE XREF: MultiplyTest+∠
    LΕ
             push
                      сх
             call
                     Multiply
             pop
                     сχ
                     short locret_620563
             jb
             loop
                     loc 620555
             clc
locret 620563:
                                      ; CODE XREF: MultiplyTest+∠
    retn
MultiplyTest endp
Multiply
                                      ; CODE XREF: MultiplyTest∠
             proc near
    , +5
                     ecx, 81h
             mov
                     eax, 417A000h
             mov
             mul
                     ecx
                     edx, 2
             CMD
             stc
                     short locret_62057F
             jnz
             cmp
                     eax, 0FE7A000h
             stc
             jnz
                     short locret 62057F
             clc
locret 62057F:
                                      ; CODE XREF: Multiply+10
                                      ; Multiply+18
             retn
Multiply
             endp
```

Indeed, if we look in the WRK¹ v1.2 source code, this code can be found easily in file WRK-v1.2\base\ntos\ke\i386\cpu.asm.

¹Windows Research Kernel

Using magic numbers while tracing

Often, our main goal is to understand how the program uses a value that was either read from file or received via network. The manual tracing of a value is often a very labour-intensive task. One of the simplest techniques for this (although not 100% reliable) is to use your own *magic number*.

This resembles X-ray computed tomography is some sense: a radiocontrast agent is injected into the patient's blood, which is then used to improve the visibility of the patient's internal structure in to the X-rays. It is well known how the blood of healthy humans percolates in the kidneys and if the agent is in the blood, it can be easily seen on tomography, how blood is percolating, and are there any stones or tumors.

We can take a 32-bit number like 0x0badf00d, or someone's birth date like 0x11101979 and write this 4-byte number to some point in a file used by the program we investigate.

Then, while tracing this program with tracer in *code coverage* mode, with the help of *grep* or just by searching in the text file (of tracing results), we can easily see where the value was used and how.

Example of *grepable* tracer results in *cc* mode:

0x150bf66 (_kziaia+0x14), e=	1 [MOV EBX, [EBP+8]] [EBP∠
<pre></pre>	1 [MOV EDX, [69AEB08h]] [69∠
0x150bf6f (_kziaia+0x1d), e=	1 [FS: MOV EAX, [2Ch]]

0x150bf75 (_kziaia+0x23), e=	1 [MOV ECX, [EAX+EDX*4]] [∠
<pre></pre>	1 [MOV [EBP-4], ECX] ECX=0∠
⊊ xf1ac360	

This can be used for network packets as well. It is important for the *magic number* to be unique and not to be present in the program's code.

Aside of the tracer, DosBox (MS-DOS emulator) in heavydebug mode is able to write information about all registers' states for each executed instruction of the program to a plain text file¹, so this technique may be useful for DOS programs as well.

¹See also my blog post about this DosBox feature: blog.yurichev.com

Other things

31.1 General idea

A reverse engineer should try to be in programmer's shoes as often as possible. To take his/her viewpoint and ask himself, how would one solve some task the specific case.

31.2 Some binary file patterns

Sometimes, we can clearly spot an array of 16/32/64-bit values visually, in hex editor. Here is an example of very typical MIPS code. As we may remember, every MIPS (and also ARM in ARM mode or ARM64) instruction has size of 32 bits (or 4 bytes), so such code is array of 32-bit values. By looking at this screenshot, we may see some kind of pattern. Vertical red lines are added for clarity:

Figure 31.1: Hiew: very typical MIPS code

31.3 Memory "snapshots" comparing

The technique of the straightforward comparison of two memory snapshots in order to see changes was often used to hack 8-bit computer games and for hacking "high score" files.

For example, if you had a loaded game on an 8-bit computer (there isn't much

memory on these, but the game usually consumes even less memory) and you know that you have now, let's say, 100 bullets, you can do a "snapshot" of all memory and back it up to some place. Then shoot once, the bullet count goes to 99, do a second "snapshot" and then compare both: the must be must be a byte somewhere which was 100 in the beginning, and now it is 99. Considering the fact that these 8-bit games were often written in assembly language and such variables were global, it can be said for sure which address in memory was holding the bullet count. If you searched for all references to the address in the disassembled game code, it was not very hard to find a piece of code decrementing the bullet count, then to write a NOP instruction there, or a couple of NOP-s, and then have a game with 100 bullets forever. Games on these 8-bit computers were commonly loaded at the constant address, also, there were not much different versions of each game (commonly just one version was popular for a long span of time), so enthusiastic gamers knew which bytes must be overwritten (using the BASIC's instruction POKE) at which address in order to hack it. This led to "cheat" lists that contained POKE instructions, published in magazines related to 8-bit games. See also: wikipedia.

Likewise, it is easy to modify "high score" files, this does not work with just 8-bit games. Notice your score count and back up the file somewhere. When the "high score" count gets different, just compare the two files, it can even be done with the DOS utility FC^1 ("high score" files are often in binary form). There will be a point where a couple of bytes are different and it is easy to see which ones are holding the score number. However, game developers are fully aware of such tricks and may defend the program against it.

31.3.1 Windows registry

It is also possible to compare the Windows registry before and after a program installation. It is a very popular method of finding which registry elements are used by the program. Probably, this is the reason why the "windows registry cleaner" shareware is so popular.

31.3.2 Blink-comparator

Comparison of files or memory snapshots remind us blink-comparator ²: a device used by astronomers in past, intended to find moving celestial objects. Blink-comparator allows to switch quickly between two photographies shot in different time, so astronomer would spot the difference visually. By the way, Pluto was discovered by blink-comparator in 1930.

Disassembler

32.1 IDA

An older freeware version is available for download ¹.

¹hex-rays.com/products/ida/support/download_freeware.shtml

Debugger

33.1 tracer

The author often use *tracer*¹ instead of a debugger.

The author of these lines stopped using a debugger eventually, since all he need from it is to spot function arguments while executing, or registers state at some point. Loading a debugger each time is too much, so a small utility called *tracer* was born. It works from command line, allows intercepting function execution, setting breakpoints at arbitrary places, reading and changing registers state, etc.

However, for learning purposes it is highly advisable to trace code in a debugger manually, watch how the registers state changes (e.g. classic SoftICE, OllyDbg, WinDbg highlight changed registers), flags, data, change them manually, watch the reaction, etc.

Questions?

Do not hesitate to mail any questions to the author: <dennis(a)yurichev.com>

Any suggestions what also should be added to my book?

Please, do not hesitate to send me any corrections (including grammar (you see how horrible my English is?)),etc.

The author is working on the book a lot, so the page and listing numbers, etc. are changing very rapidly. Please, do not refer to page and listing numbers in your emails to me. There is a much simpler method: make a screenshot of the page, in a graphics editor underline the place where you see the error, and send it to me. He'll fix it much faster. And if you familiar with git and \angle TEX you can fix the error right in the source code: GitHub.

Do not worry to bother me while writing me about any petty mistakes you found, even if you are not very confident. I'm writing for beginners, after all, so beginners' opinions and comments are crucial for my job.

Warning: this is a shortened LITE-version!

It is approximately 6 times shorter than full version (~150 pages) and intended to those who wants for very quick introduction to reverse engineering basics. There are nothing about MIPS, ARM, OllyDBG, GCC, GDB, IDA, there are no exercises, examples, etc.

If you still interesting in reverse engineering, full version of the book is always available on my website: beginners.re.

Acronyms used

CHAPTER 39. QUESTIONS?	CHAPTER 39. QUESTIONS?
OS Operating System	xi
PL Programming language	
ROM Read-only memory	
RA Return Address	66
SP stack pointer. SP/ESP/RSP in x86/x64. SP in ARM	
PC Program Counter. IP/EIP/RIP in x86/64. PC in ARM	
IDA Interactive Disassembler and debugger developed b	y Hex-Rays
MSVC Microsoft Visual C++	
AKA Also Known As	
CRT C runtime library	9
CPU Central processing unit	xi
SIMD Single instruction, multiple data	80
DBMS Database management systems	ix
ISA Instruction Set Architecture	
SEH Structured Exception Handling	19
NOP No OPeration	
RAM Random-access memory	
API Application programming interface	163

EOF End of file	

Glossary

real number numbers which may contain a dot. this is *float* and *double* in C/C++. 92

decrement Decrease by 1. 77, 86, 189

increment Increase by 1. 77, 86

product Multiplication result. 41

stack pointer A register pointing to a place in the stack. 9, 13, 17, 22, 203

quotient Division result. 92

anti-pattern Generally considered as bad practice. 30, 159

callee A function being called by another. 11, 16, 26, 27, 35, 40, 42, 66, 154, 159

caller A function calling another. 5, 9, 35, 40, 41, 44, 66, 154

- heap usually, a big chunk of memory provided by the OS so that applications can divide it by themselves as they wish. malloc()/free() work with the heap. 14, 16, 132
- **jump offset** a part of the JMP or Jcc instruction's opcode, to be added to the address of the next instruction, and this is how the new PC^1 is calculated. May be negative as well. 38, 54

NOP "no operation", idle instruction. 189

PDB (Win32) Debugging information file, usually just function names, but sometimes also function arguments and local variables names. 162

POKE BASIC language instruction for writing a byte at a specific address. 189

¹Program Counter. IP/EIP/RIP in x86/64. PC in ARM.

register allocator The part of the compiler that assigns CPU registers to local variables. 86, 154

- **reverse engineering** act of understanding how the thing works, sometimes in order to clone it. iv
- **stack frame** A part of the stack that contains information specific to the current function: local variables, function arguments, RA, etc. 28, 41
- **stdout** standard output. 18, 66
- **tracer** My own simple debugging tool. You can read more about it here: 33.1 on page 192. 165, 180, 185, 186

Windows NT Windows NT, 2000, XP, Vista, 7, 8. 170
